PAPERS OF THE SOCIETY FOR GYNECOLOGIC INVESTIGATION

Elevated fetal plasma lactate produces polyhydramnios in the sheep

Theresa L. Powell, PhD, and Robert A. Brace, PhD

San Diego, California

In human fetuses with hemolytic diseases such as erythroblastosis fetalis, hydrops fetalis or polyhydramnios often develops. The mechanism(s) that produces these fluid imbalances is unknown, although lactate concentrations have been reported to be elevated in hydropic human fetuses with erythroblastosis. In this study we explored the role of lactate in producing fetal fluid imbalances. In seven near-term fetal sheep, we infused 5 mol/L sodium lactate at a rate of 10 mmol/hr for 3 days. Fetal plasma lactate rose by 6.0 ± 1.0 (mean ± SE) mmol/L above control. Fetal plasma osmolality and Na+ increased slightly, CI⁻ decreased, and bicarbonate rose in proportion to the CI⁻ decrease. Fetal renal lactate excretion was 1.1 ± 0.3 mmol/hr while Na+ excretion was 10.6 ± 1.9 mEg/hr. Fetal urine flow increased by 1.9 \pm 0.4 L/day and the urine remained hypotonic relative to fetal plasma throughout the infusion. Amniotic fluid lactate and Na+ rose during the infusion period and remained elevated during a 24-hour recovery period. Amniotic plus allantoic fluid volume at autopsy was 5.3 ± 0.8 L compared with a normal of 0.5 to 1.0 L. There was little evidence of fetal edema. In summary, a moderate sustained elevation in fetal plasma lactate concentration appears to be a powerful osmotic agent for fetal accumulation of fluid from the maternal compartment over a period of days. This may be the primary mechanism whereby hydrops fetalis or polyhydramnios develops in severely anemic human fetuses, (AM J OBSTET GYNECOL 1991;165:1595-1607.)

Key words: Hydrops fetalis, erythroblastosis fetalis, sheep, fluid dynamics, urinary output, edema, amniotic fluid volume

Hydrops fetalis (severe fetal edema) and polydramnios (excessive amniotic fluid volume) often occur concomitantly with hemolytic anemias, but the mechanism(s) that produces these two conditions is unknown. Recent studies of erythroblastotic human fetuses^{1,2} have reported an elevated fetal plasma lactate concentration correlated inversely with plasma hemoglobin concentration and oxygen content. The critical values for oxygen content (2 mmol/L), hemoglobin concentration (4 gm/dl), and oxygen delivery rate (14 ml/kg/min)³ necessary to maintain adequate fetal tissue oxygenation also have been determined. These data, along with studies of blood flow during severe hypoxia,⁴ suggest that as the fetus becomes severely anemic and oxygen delivery drops below the critical level, a redistribution

of blood flow occurs. Systemic tissues then become hypoxic and begin producing lactate. In humans, only those fetuses with plasma lactate elevated to three to five times normal (i.e., 3 to 10 mmol/L) were hydropic.¹ The importance of this observation is that it may provide a mechanism for the development of hydrops or polyhydramnios; that is, as lactate accumulates in the fetal plasma, it may act osmotically to draw fluid from the maternal to the fetal circulation. The potential for producing fetal fluid imbalance stems from the fact that each millimole per liter increase in lactate at fetal body temperature could generate approximately 20 mm Hg osmotic pressure. This could provide a substantial driving force for water accumulation by the fetus.

The purpose of this study was to determine the role of elevated fetal plasma lactate in the development of hydrops fetalis and polyhydramnios. To study this, we infused concentrated sodium lactate (pH, 5.0) intravascularly into near-term fetal sheep at a rate sufficient to increase the plasma lactate concentration to three to-five times normal, i.e., comparable to the levels seen in edematous, anemic human fetuses. The infusion was continued for 3 days, during which time the fetuses were monitored closely and examined daily by ultrasonography for the development of polyhydramnios or ascites. The hypothesis was that lactate would act os-

motically to draw fluid from the maternal to the fetal circulation, potentially resulting in fetal edema, ascites formation, and an increased amniotic fluid volume.

Material and methods

Surgery and postoperative care. Seven pregnant ewes (gestational age at surgery 124 ± 1 days, mean \pm SE) were used in these studies. All procedures and experiments decribed in this study are in accordance with and have been approved by the University of California at San Diego Animal Subjects Committee. The experiments are in compliance with the National Institutes of Health guidelines for the care and use of laboratory animals.

Food was withheld 24 hours before surgery. Atropine (1 mg) was administered 30 minutes before surgery (intramuscularly) to reduce respiratory and gastric secretions during anesthesia. 5 Anesthesia was induced with 1 gm thiamylal sodium (Biotal, Bio-Ceutic) given intravenously; the animal was intubated and anesthesia was maintained with 0.5% to 1.5% halothane in oxygen. Indwelling catheters were aseptically placed in one maternal femoral artery and vein. Maternal heart rate and arterial pressure were monitored continuously during surgery, and the ewe received 1 L of lactated Ringer's solution with 5% dextrose intravenously during surgery. One liter of warmed lactated Ringer's solution was administered intravenously to the ewe, and 500 ml of warmed normal saline solution was administered to the amniotic space 2 hours after surgery to replace any fluids that might have been lost during surgery.

The surgical procedure involved exposing the fetus, to the level of the groin, through a uterine incision. Fetal femoral catheters were inserted bilaterally to the level of the diaphragm in the descending aorta and inferior vena cava. To expose the bladder, a suprapubic

abdominal incision of the fetus was performed. The bladder was incised; a catheter was inserted and secured by a purse-string ligature, and the abdomen was closed. Two amniotic fluid catheters were sutured to the fetal skin. The fetal membranes and uterus were closed separately, with care being taken to ensure there were no leaks in the membranes or uterus. All catheters were exteriorized into a cloth pouch secured to the flank of the ewe and all incisions were closed.

Vascular catheters were flushed daily with heparin sodium (1000 U/ml) to maintain patency. Fetuses received 0.4 gm ticarcillin and 13.4 mg clavulanate (a β -lactamase inhibitor) daily by an amniotic catheter, and the ewes received 500,000 U penicillin and 625 mg streptomycin (intramuscularly) daily for the first 5 post-operative days.

Experimental protocol. Experiments began 5 days after surgery. The protocol, illustrated in Fig. 1, consisted of a 24-hour control period, a 72-hour infusion period, and a 24-hour recovery period. Sample times during the 5-day study are indicated on Fig. 1. This experimental protocol was the same as that used in our recent study in which 5 mol/L sodium chloride was infused into ovine fetuses.6 In this study an infusion of 5 mol/L sodium chloride lactate into a fetal vein at a rate of 10 mmol/hr (volume approximately 2 ml/hr) was initiated at 9 AM (1 hour after the second control sample). Initially, the lactic acid infusate was titrated to a pH of approximately 7.0 by adding sodium hydroxide pellets. Infusion of this resulted in severe alkalosis of the fetus; those fetuses are not included in the results of this study. Subsequently the infusate was titrated to a pH of approximately 5.0. Throughout the first day fetal arterial blood lactate was monitored and the infusion rate altered if necessary to achieve a plasma lactate level of 5 to 10 mmol/L, i.e., a level comparable to

Table I. Values during 24-hour control period

Variable	Maternal blood	Fetal blood	Fetal urine	Amniotic fluid
Arterial pH	7.44 ± 0.01	7.33 ± 0.01		
Pco ₂ (mm Hg)	38.4 ± 1.6	53.3 ± 1.1		E-1-400

Values are mean \pm SE, n = 7.

that seen in hydropic human fetuses with erythroblastosis. ^{1, 2} In one fetus the rate was lowered to 8.6 mmol/hr and in another the rate was increased to 11.3 mmol/hr to achieve the desired lactate concentration.

At each sample time, fetal arterial blood (3 ml), maternal arterial blood (1 ml), amniotic fluid (1 ml), and fetal urine (1 ml) were collected. Fetal blood removed during sampling was replaced with an equal volume of heparinized maternal blood. Urine flow rate (by direct collection after emptying the bladder⁷) and estimated amniotic plus allantoic fluid volume were determined at each sample time. The estimation of amniotic plus allantoic fluid volume by ultrasonography was accomplished by dividing the abdomen into four equal quadrants and scanning each quadrant for fluid pockets. The largest vertical column of fluid in each of the four quadrants was summed for an amniotic fluid index and was determined in triplicate.8 In sheep, this technique allows for estimation of the total amniotic plus allantoic fluid volumes and examination of the fetus for edema. Preliminary studies in humans and sheep have shown high correlations between the amniotic fluid index and directly measured amniotic fluid volumes.9 In this study each millimeter increase in the amniotic fluid volume corresponded to an increase in amniotic fluid volume of approximately 45 ml.

At the end of the experiment the animal was killed with pentobarbital sodium (100 mg/kg) and autopsy was performed. The amniotic plus allantoic fluid volume was measured at autopsy by direct collection, and fetal weight was determined.

Analytic measurements. All samples were analyzed for osmolality (Advanced Instruments, model 3D2), Na⁺, Cl⁻, and K⁺ (Nova Biomedical, model 5+5 electrolyte analyzer), lactate, and glucose (YSI model 2300). Maternal and fetal blood samples were also analyzed for pH, PO₂, and PCO₂ (39° and 39.5° C, respectively (Instrumentation Laboratories, model 1302), hematocrit in triplicate, and plasma protein (Reichert TS meter).

Data analysis and calculations. All data are pre-

sented as mean \pm SE or as a mean change \pm SE from the average value during the control period, unless otherwise specified. Data were analyzed by two-way analysis of variance for repeated measures with p < 0.05 considered statistically significant. Values in the results are averages during the 3 days of sodium lactate infusion unless specified otherwise.

The change in fetal blood volume was estimated from the hematocrit, as previously described. ¹⁰ This technique is valid because the ovine fetus does not have a releasable store of red blood cells. ¹⁰ The technique also has the advantage that changes in red blood cell mass with growth are taken into account, and only deviations from the normal increase are detected. Estimated fetal extracellular fluid volume was calculated from plasma protein concentrations. ¹¹ This calculation is based on the assumption that plasma proteins rapidly distribute between the interstitial space and plasma because of a capillary permeability to proteins in the fetus fifteen times that of the adult. ¹² The accuracy of this estimation is unknown. However, large changes in extracellular fluid volume should be readily detected.

Maternal and fetal bicarbonate were calculated from the respective PCO_2 and pH with the equation¹³: Bicarbonate = $0.029131 \times PCO_2^{(-5.0844 + 0.6854 \text{ pH} + 0.0242 \text{ pH}^2)}$ (corrected to 39.5° C).

Results

The mean values for all variables during the 24-hour control period are presented in Table I. These values are within the normal range for late-gestation fetuses as measured in our laboratory. Control urine flow was 0.64 ± 0.10 ml/min (mean \pm SE), and fetal weight at autopsy was 3.5 ± 0.3 kg at a gestational age of 135 ± 1 days.

The infusion of 10 mmol/hr sodium lactate (pH 5.0) into the fetal circulation resulted in a slight alkalosis (Fig. 2, A), with the mean increase in fetal pH of 0.10 ± 0.01 pH units (p < 0.0001) during the 3-day infusion. As seen in Fig. 2, B and C, the fetal PCo₂

1598 Powell and Brace December 1991
Am J Obstet Gynecol

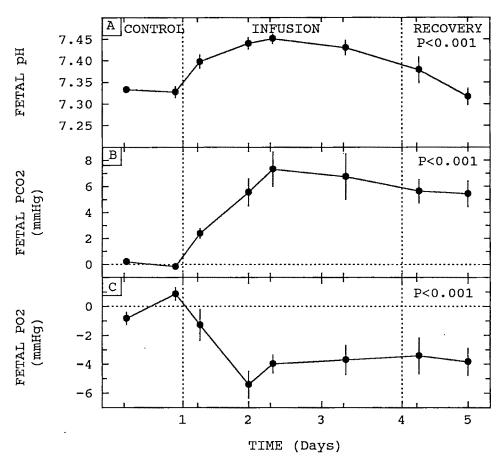

Fig. 2. Mean \pm SE fetal pH (A) and mean \pm SE changes from control in PCO₂ (B) and PO₂ (C) during infusion of 5 mol/L sodium lactate to fetus.

increased (5.5 \pm 1.2 mm Hg, p < 0.0001) and the Po₂ decreased (3.6 \pm 0.9 mm Hg, p < 0.0001) during the infusion.

Fig. 3 is a summary of the changes from control levels in fetal plasma composition. Fetal plasma osmolality (Fig. 3, A) rose by a mean of 7.8 \pm 1.4 mOsm/kg (p < 0.0001) over the 3-day infusion. Fetal Na⁺ (Fig. 3, B) increased only slightly (1.4 \pm 0.5 mEq/L, p < 0.001) and fetal Cl⁻ (Fig. 3, C) decreased dramatically (14.6 \pm 2.2 mEq/L, p < 0.0001) during the sodium lactate infusion. Lactate (Fig. 3, D) increased by a mean of 6.0 \pm 0.9 mmol/L (p < 0.0001). Fetal plasma bicarbonate (Fig. 3, E) also was elevated (10.9 \pm 1.2 mmol/L, p < 0.0001). In addition to these changes, fetal plasma K⁺ decreased by 1.04 \pm 0.09 mEq/L (p < 0.0001), and glucose did not change.

None of the maternal variables showed a statistically significant change during the 72-hour sodium lactate infusion. However, the maternal lactate decreased by 0.20 \pm 0.09 mmol/L during the infusion (p=0.06). In addition, maternal plasma Cl⁻ was significantly reduced during the recovery period (3.4 \pm 1.7 mEq/L, p<0.006).

The osmotic and concentration gradients across the

placenta (fetal minus maternal) are shown in Fig. 4. A reversal of the transplacental osmotic gradient (from -1.8 ± 1.3 to $+7.5 \pm 1.9$ mOsm/kg) in favor of increased fluid acquisition by the fetus is seen in Fig. 4, A. The infusion of sodium lactate resulted in a reduction (27%) in the transplacental Na+ concentration gradient but not a reversal (Fig. 4, B). The Cl- concentration gradient across the placenta was the most significantly enhanced of the electrolyte gradients (Fig. 4, C). Control fetal Cl⁻ was -5.8 ± 0.9 mEq/L lower than maternal Cl-. As the fetal Cl- decreased during the infusion, the Cl- gradient across the placenta increased to an average of -19.5 ± 2.6 mEq/L over the 3-day infusion. A small concentration gradient of 0.35 ± 0.18 mmol/L existed for lactate in the control period and, as the lactate increased during the 3-day infusion, the concentration gradient toward the mother was increased to $6.6 \pm 0.9 \, \text{mmol/L}$ (Fig. 4, D). Finally, the transplacental bicarbonate concentration gradient was significantly increased (1.6 \pm 0.9 to 12.5 \pm 1.1 mEq/L, p < 0.0001) (Fig. 4, E) favoring loss of bicarbonate to the maternal circulation.

Fetal blood volume as seen in Fig. 5, A, showed no change during the first 2 days of infusion. During the

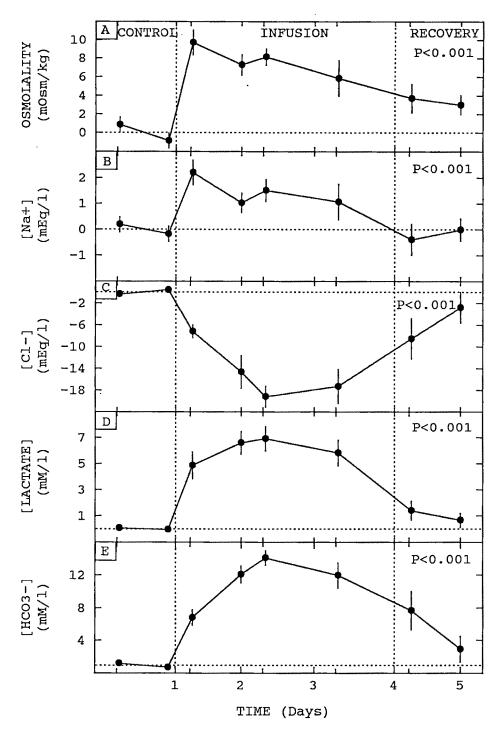

Fig. 3. Mean ± SE changes from control in fetal blood osmolality (A), Na* (B), Cl- (C), lactate (D), and bicarbonate (E) during sodium lactate infusion.

third day and throughout the recovery period, blood volume decreased significantly (p < 0.0001), averaging $9.9\% \pm 2.5\%$ below control at the end of the recovery period. Changes in estimated fetal extracellular fluid volume underwent a pattern similar to the changes seen in blood volume (Fig. 5, B) except that the rise in extracellular fluid volume during the infusion period $(7.8\% \pm 2.3\%)$ was statistically significant (p < 0.0001),

and the decline during the recovery period was not as extensive (5.8% \pm 2.3%). No ascites or pleural effusions were seen during the daily ultrasonography examinations.

Urine composition changes are shown in Fig. 6. Although the urine osmolality (Fig. 6, A) rose by a mean of $66.4 \pm 9.5 \text{ mOsm/kg}$ (p < 0.0001) during the infusion, the urine remained hypotonic relative to fetal 1600 Powell and Brace

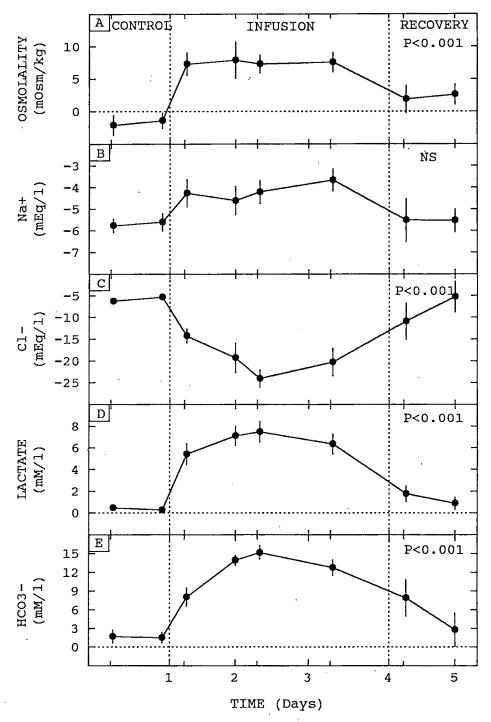

Fig. 4. Mean \pm SE in transplacental (fetal minus maternal) osmotic (A) and concentration gradients for Na⁺ (B), Cl⁻ (C), lactate (D), and bicarbonate (E) during 5 mol/L sodium lactate infusion.

blood throughout the experiment. Urine Na⁺ (Fig. 6, B) accounted for the majority of the increase in osmolality as it increased by 46.4 ± 4.5 mEq/L (p < 0.0001), whereas urine lactate (Fig. 6, D) increased by only 9.7 ± 3.1 mmol/L (p < 0.0001). Urine Cl⁻ (Fig. 6, C) was not significantly altered during the infusion. The mean control value for urine pH was 7.32 ± 0.15 , and the urine pH rose by 0.73 ± 0.17 pH

units during the infusion (p < 0.0001). In addition to the changes seen in urine composition, the urine production rate (Fig. 7, A) increased by a mean of 1.9 ± 0.4 L/day (p < 0.0001). As seen in Fig. 7, B, all the infused Na⁺ was excreted in the urine (10.8 ± 1.9 mEq/hr mean increase above control). Lactate excretion (Fig. 7, D), on the other hand, rose by 1.1 ± 0.3 mmol/hr, indicating that only 11.4% of the infused

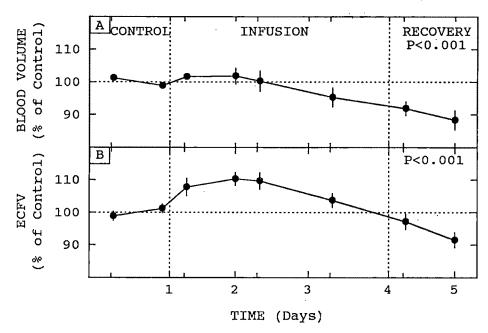

Fig. 5. Mean ± SE fetal blood volume (A) and estimated extracellular fluid volume (ECFV) (B) expressed as percent of control.

lactate was excreted in the urine. Urinary Cl- excretion (Fig. 7, C) rose by 5.0 ± 0.9 mEq/hr during the infusion.

Amniotic fluid osmolality (Fig. 8, A) remained unchanged throughout the procedure. However, amniotic Na⁺ $(6.4 \pm 2.1 \text{ mEq/L}, p < 0.001)$ and lactate $(7.9 \pm 2.0 \text{ mEq/L}, p < 0.001)$ increased (Figs. 8, B and D) and remained elevated throughout the recovery period. Amniotic fluid Cl- decreased by a mean of $15.6 \pm 3.7 \text{ mEq/L}$ (p < 0.0001). In addition, the amniotic fluid index (Fig. 9) rose throughout the duration of the experiment and remained elevated during the recovery period (85% \pm 14%, p < 0.0001). At autopsy a mean of 5.3 ± 0.8 L of amniotic plus allantoic fluid was collected from the uterine compartment. This volume would contain roughly 650 mmol Na+, 70 mmol lactate and, 450 mmol Cl,- on the basis of amniotic fluid concentrations at the final sample. Compared with the approximately 720 mmol that was infused, this accounts for roughly 77.6% and 9.6% of the infused Na+ and lactate, respectively.

Comment

The underlying mechanisms that produce hydrops fetalis or polyhydramnios in the human fetus are unknown. The data from two recent reports1.2 suggest that hydrops occurs during erythroblastosis fetalis only in those fetuses with elevated plasma lactate concentrations. This observation led us to hypothesize that the elevated lactate level could produce these fetal fluid imbalances because it could act osmotically to draw water from the maternal to the fetal compartment. This is supported by Hansen and Gest¹⁴ in a review of hydrops fetal in which they suggest that osmotically active substances accumulate in the blood of the fetus when oxygen delivery is reduced. The results of our study support this hypothesis, in that the infusion of 5 mmol/L sodium lactate for 3 days resulted in extensive polyhydramnios. Urine production increased by 1.9 ± 0.4 L/day above control. Over 3 days of infusion this would be an increase of 5.7 ± 1.2 L. The amniotic plus allantoic fluid volume measured at autopsy was 5.3 ± 0.8 L, compared with a normal of 0.5 to 1.0 L.¹⁵ Therefore large amounts of fluid were crossing the placenta, entering the fetal vasculature, and being excreted in the form of dilute urine, which remained in the amniotic and allantoic fluid compartments.

The driving force for this fluid accumulation could be either the general effects of an increase in fetal osmolality or the specific effects of an elevated fetal plasma lactate level. In a recent study in which we infused comparable amounts of sodium chloride into fetal sheep for 3 days, neither polyhydramnios nor hydrops developed.6 Increases in fetal osmolality and Na+ with sodium chloride infusion were similar to those observed in this study. Additionally, urine production increased to 3.5 L/day during the sodium chloride infusion. Thus it appears that the presently observed accumulation of 4 to 5 liters of excess fluid was due to the specific effects of the lactate. This is consistent with previous reports suggesting that Na+ and Cl- cross the placenta¹⁵ but that lactate does not.¹⁷ Other osmotic agents have not, to our knowledge, been examined for their ability to produce polyhydramnios or hydrops fe1602 Powell and Brace December 1991

talis during long-term infusions. It seems likely that other osmotically active substances that have limited placental permeability and are effectively excreted by the fetal kidney would lead to polyhydramnios, e.g., mannitol. However, infusion of sodium chloride did not result in polyhydramnios,⁶ most likely because sodium chloride more readily crosses the placenta.

It should be questioned whether the observed fluid accumulation is consistent with that predicted from the placental filtration coefficient and changes in placental lactate. The filtration coefficient for the sheep placenta has been estimated to be 0.0067¹⁸ or 0.026¹⁹ ml/min/kg/mm Hg. On the basis of an increase in lactate of 6.6 mmol/L, the total amount of water crossing the placenta would be 13.2 or 51.2 L over 3 days. Clearly the observed volume accumulation is not out-

side of the range predicted and further suggests that factors other than lactate are involved in water transport across the placenta during this experiment.

The changes in fetal Cl⁻ during the sodium lactate infusion were quite dramatic. The decreased Cl⁻ resulted in the largest steady-state transplacental Cl⁻ concentration gradient ever reported in the sheep. The increased fetal urine flow was associated with a 5.0 mEq/hr increase in Cl⁻ excretion even though urine Cl⁻ did not change. On the basis of plasma Cl⁻ changes, the loss of Cl⁻ from the fetal extracellular fluid compartment would be negligible compared with the total amount excreted. On the basis of mean Cl⁻ transplacental concentration gradient during the infusion, the published placental permeability coefficient for Cl⁻ (0.0098 ml/sec/kg),¹⁶ and the mean fetal weight at au-

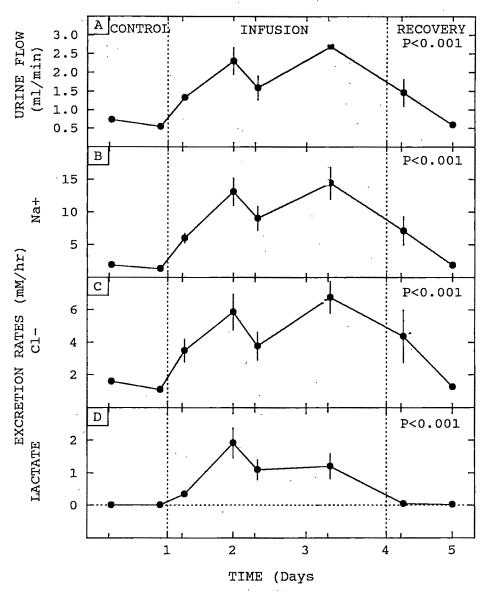

Fig. 7. Urine flow rate (A) and urinary excretion rate for Na⁺ (3), Cl⁻ (C), and lactate (D) during infusion of sodium lactate at a rate of 10 mmol/hr.

topsy, the transfer of CI- across the placenta would have been 2.4 mEq/hr. These data indicate that the drop in fetal plasma Cl- may have been due to a low placental permeability. However, to account for the observed renal excretion of Cl-, the permeability, of the placenta for Cl⁻ must be at least twice the previously reported value. This is also supported by the accumulation of 450 mEq of Cl⁻ in the amniotic plus allantoic compartments. Overall, it would appear that the fetus excretes the infused Na+ accompanied by several anions, i.e., lactate, bicarbonate, and Cl-.

In previous studies in which lactate tagged with carbon 14 was infused into fetal sheep, ≥90% of the infused lactate was metabolized20 when lactate levels were elevated. The increased Pco2, and bicarbonate and the decreased Po2 seen in this study suggest that similar amounts of lactate were metabolized. This is consistent with our observation that 10% of the infused lactate wa excreted in the fetal urine. Bicarbonate concentrations were greatly increased during the sodium lactate infision, and the fetuses became alkalotic. This is most lilely related to the metabolism of the infused lactate, b-cause metabolism of an anion produces an anion as a by-product. The decreased Cl- also may cause bicarbonate to increase. Urinary bicarbonate excretion was elevated on the basis increased of pH of the fetal urine. The increase in PCO2 would promote removal across the placenta of the metabolic by-products of l_ctate utilization. Furthermore, the elevated bicarbon te may be exerting an osmotic force for water accumulation across the placenta. This possibility is supported by a model for water transfer across the

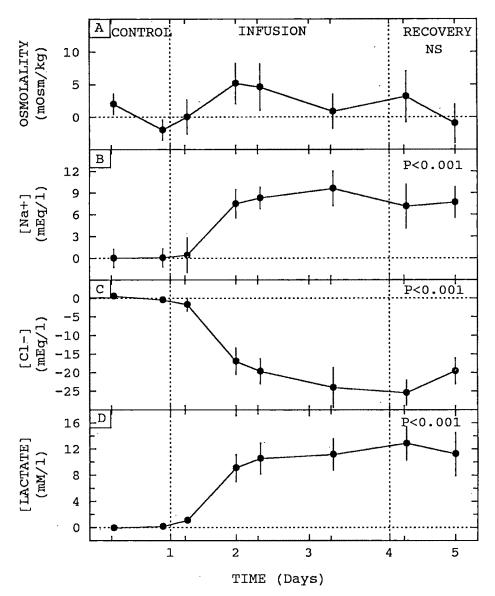

Fig. 8. Amniotic fluid osmolality (A), Na⁺ (B), Cl⁻ (C), and lactate (D) expressed as mean \pm SE change from control during infusion of sodium lactate.

human placenta developed by Wilbur et al.,21 in which bicarbonate was proposed as a major osmotic agent for water accumulation by the fetus. In their computer testing of this theory, bicarbonate and other substances that are present in higher concentrations in the fetus than in the mother (i.e., carbon dioxide, urea, fructose, and actively transported solutes such as Ca++ and amino acids) exerted the major driving force for water gain by the fetus. This theory was tested in a computer model for water transfer across the sheep placenta.22 In that evaluation Faber and Anderson²² concluded that the effects of changes in bicarbonate were for the most part counterbalanced by changes in the sodium chloride gradient across the placenta. Therefore, bicarbonate was thought to have only a modest effect on water transport.

The hypoxia experienced by these fetuses may have

been a sufficient stimulus to accelerate red blood cell production, because previous studies have suggested fetal red blood cell production can be augmented in as little as 3 to 5 days.23 We believe the decrease in the calculated blood volume on the third day of infusion and throughout the recovery period may be to an increased red blood cell volume relative to plasma volume and does not necessarily reflect a true decrease in blood volume. The 8% increase in estimated extracellular fluid volume observed in this study relative to the lack of change initially in blood volume suggests a true increase in extracellular fluid volume but does not represent extensive edema formation. This is supported by the fact that fetuses were examined daily by ultrasonography and no ascites or pleural effusions were observed.

In human fetuses with isoimmunization, hydrops will

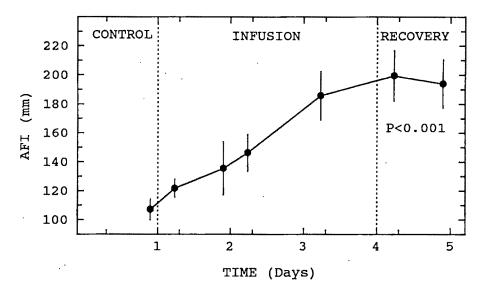

Fig. 9. Amniotic fluid index (AFI) responses of amniotic plus allantoic fluid volume by ultrasonography during infusion of sodium lactate.

develop in approximately 25%, and 75% of those will have polyhydramnios.¹⁴ In addition, polyhydramnios often occurs with mild to moderate edema associated with anemia²⁴ and sometimes precedes the development of hydrops. In our study we expected hydrops to develop in the sheep fetuses but found mild edema at most and massive polyhydramnios. It is possible that, given more time, the fetuses in this study may have become edematous. On the other hand, the tremendous ability of urine production to increase in the nearterm sheep fetus would tend to promote the development of polyhydramnios, rather than hydrops, in this study. The fact that edema develops in human fetuses suggests that the kidney of the erythroblastotic human fetus with an elevated lactate level may not be able to excrete excess fluid as effectively as that of the nearterm sheep fetus. In addition, the stress of hypoxia caused by anemia may result in elevated arginine vasopressin concentrations in the human fetus, thereby producing an antidiuresis that would contribute to hydrops formation. When the sheep fetus experiences severe hypoxemia, there is an increase in arterial pressure, a decrease in renal blood flow, and an increase in renal vascular resistance.25 These changes are associated with increases in plasma epinephrine, arginine vasopressin, and plasma renin activity25 and could promote edema formation. Because the fetuses in this study had only mild hypoxia and their renal function was not impaired, as evidenced by the increased urine production, polyhydramnios rather than hydrops developed.

This study represents an attempt to isolate the osmotic effects of increased lactate seen in hydropic human fetuses. Although there is no evidence that the infusion of sodium lactate will mimic the conditions of severely anemic fetuses, we believe that lactate is a

powerful osmotic agent in the fetus, although other factors are clearly involved in altering the fluid distribution. For example, there are circumstances in both sheep and human fetuses in which the plasma lactate level is elevated with no indication of either hydrops or polyhydramnios.26-30 Hypoxemia in sheep fetuses results in an increase in fetal lactate concentration, but changes in amniotic fluid volume were not explored in these studies. The lack of hydrops formation with elevated lactate levels in hypoxic fetuses and the results of our study suggest that elevated plasma lactate levels alone may not account for hydrops formation in erythroblastotic human fetuses. Other components necessary for the development of hydrops in erythroblastosis remain unknown. However, we have shown that lactate can act osmotically to increase the fluid content of the fetal compartment. This, along with other physiologic alterations occurring in severely anemic fetuses, such as reduced renal function and elevated vasoactive or antidiuretic hormone concentrations, could explain the formation of hydrops in these fetuses.

The amniotic fluid osmolality did not change even though extensive fluid accumulation occurred. This is rather surprising in light of the tremendous volume of dilute urine that entered that compartment during the infusion. The amniotic fluid compositional changes indicate nearly all of the excreted lactate remained in the amniotic fluid. It would appear that bicarbonate also was elevated and that these two anions compensated for the decreased Cl... The fact that amniotic plus allantoic fluid volume was elevated in response to sodium lactate but not sodium chloride infusion⁶ suggests that the lactate and bicarbonate may be acting osmotically to retain fluid in the amniotic space. This may be due to a low permeability of the pathway for direct exchange of lactate between amniotic fluid and the fetal blood perfusing the intramembranous pathway.³¹ Our laboratory has shown that water directly enters the fetal vasculature from the amniotic fluid independent of fetal swallowing and that Na⁺ and Cl⁻ may move relatively easily across this pathway.¹⁹ By comparison, this study suggests that the intramembranous pathway may be relatively impermeable to lactate. This is supported by the fact that amniotic fluid lactate concentrations under basal conditions are higher than concentrations in fetal blood, fetal urine, or allantoic fluid and by the finding in this study that nearly all of the excreted lactate remained in the amniotic compartment.

The regulation of composition and volume of amniotic fluid is not clearly understood. It appears from the sodium chloride and sodium lactate infusion studies that amniotic fluid osmolality is conserved in the face of tremendous changes in volume or fetal urine flow rate. The entry of large volumes of urine and perhaps some lung secretions and direct exchange between the fetal blood and amniotic fluid across the fetal membranes all contribute to varying degrees. From this study, it appears that amniotic Cl⁻ was not tightly regulated as Cl⁻ decreased, even though the urinary excretion of Cl⁻ was increased. Alternatively, as lactate and bicarbonate accumulated in the amniotic fluid, the Cl⁻ may have decreased to maintain electrical neutrality.

In conclusion, this study suggests that alterations in fetal plasma lactate concentration may be a major determinant of fetal fluid imbalances. Moderate, sustained elevations in fetal plasma lactate concentration proved to be a powerful osmotic agent in the sheep fetus, in that large volumes of fluid were accumulated in the fetal compartment. This study demonstrates the accumulation of fluid in the fetal compartment during sodium lactate infusion was due specifically to lactate or its metabolic by-products because comparable infusions of sodium chloride did not result in fluid accumulation. Thus elevations in fetal lactate concentration and its metabolic by-products may be the primary underlying mechanism for fetal fluid imbalances seen in erythroblastotic human fetuses.

We thank Kathy Aoyama and Wendy Ewing for their technical assistance.

Left thoracic duct lymph flow responses to angiotensin II or atrial natriuretic factor infusion in the ovine fetus

Robert A. Brace, PhD, and Robert L. Andres, MD

San Diego, California

In the ovine fetus it is known that left thoracic duct lymph flow rate relative to body weight is four to five times adult levels, but it is not known whether the circulating hormones modulate fetal lymph flow. To explore this, we intravenously infused either angiotensin II (10 to 400 ng/min, n = 8) or atrial natriuretic factor (500 to 1000 ng/min, n = 8) into chronically catheterized fetal sheep for 30 minutes. Significant increases occurred in fetal arterial (p < 0.0001) and venous (p = 0.018) pressures during the angiotensin II infusion, and thoracic duct lymph flow rate underwent a dose-dependent increase (r = 0.888, p = 0.0033). With termination of the angiotensin II infusion, fetal vascular pressures rapidly returned to control levels, and lymph flow fell from 18.8% ± 10.1% (mean ± SE) above control to 13.7% ± 7.7% below preinfusion levels (ρ < 0.01). During the atrial natriuretic factor infusion, fetal arterial pressure and circulating blood volume decreased significantly (p < 0.01), whereas thoracic duct lymph flow was unchanged. After termination of the atrial natriuretic factor infusion, fetal arterial pressure returned toward control, blood volume remained reduced, and lymph flow rate underwent a transient rise to $35.6\% \pm 15.7\%$ (p < 0.05) above control levels. These data suggest that angiotensin II and atrial natriuretic factor have significant but opposite effects on fetal thoracic duct lymph flow rate, with angiotensin II stimulating and atrial natriuretic factor suppressing lymph flow. (AM J OBSTET GYNECOL 1991;165:1607-13.)

The lymphatic system plays an important role in maintaining fluid balance by returning both fluid and protein to the circulation. Although the lymphatic system of the adult has been explored in a large number of studies,1 relatively little attention has been paid to the lymphatic system of the fetus. It is known that in the chronically catheterized ovine fetus left thoracic duct lymph flow rate averages four to five times adult levels relative to body weight.2,3 It also is known that 508 Brace and Andres December 1991

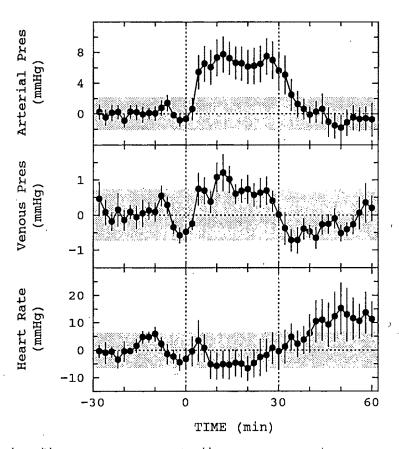

Fig. 1. Fetal arterial pressure, venous pressure, and heart rate responses to intravenous angiotensin II infusion ($210 \pm 60 \text{ ng/min}$, n = 8) from 0 to 30 minutes. Data are mean \pm SE change from mean value during 30-minute preinfusion period. Shaded area, 95% Confidence interval around preinfusion value.

Table I. Control fetal values during 30-minute preinfusion period

Variable	Mean ± SE*
Arterial pressure (mm Hg)	47.9 ± 1.4
Venous pressure (mm Hg)	3.0 ± 0.2
Heart rate (beats/min)	160 ± 5
Lymph flow rate (ml/min)	0.58 ± 0.07
Arterial pH	7.340 ± 0.015
Carbon dioxide tension (mm Hg)	54.2 ± 1.8
Oxygen tension (mm Hg)	23.7 ± 1.0
Hematocrit (%)	35.9 ± 1.3
Plasma protein concentration (gm/dl)	3.63 ± 0.08
Lymph protein concentration (gm/dl)	2.56 ± 0.09

*Combined data from angiotensin II— and ANF-infused fetuses; n = 16 for continuously measured variables and n = 12 for data derived from blood and lymph samples.

fetal thoracic duct lymph flow rate increases after vascular volume loading³ and decreases with elevations in venous pressure.^{4,5} In the adult, a variety of vasoactive hormones, including angiotensin II and the catecholamines,^{1,6,7} have been reported to alter lymph flow or lymphatic function. In addition, atrial natriuretic factor (ANF) has been reported to decrease the contractility of lymphatic vessels isolated from lambs.⁸ These observations, coupled with the fact that the above hormones have cardiovascular actions in the fetus similar to those in the adult, raise the possibility that vasoactive hormones may modulate lymphatic function in the fetus. To explore this hypothesis, we infused angiotensin II or ANF into chronically catheterized ovine fetuses while simultaneously measuring left thoracic duct lymph flow rate.

Material and methods

Animal preparation and maintenance. Sixteen fetal sheep at 126 to 133 days' gestation at the time of surgery were surgically prepared and maintained postoperatively as previously described in detail elsewhere.² Briefly, with the animals under gas inhalation anesthesia and with strict aseptic techniques, catheters were placed in the fetal descending and ascending aorta, inferior and superior vena cava, and amniotic space. An additional large-diameter catheter was placed in the left thoracic lymph duct at the base of the neck just distal to its junction with the left cervical and brachiocephalic lymph ducts and jugular vein.² Postoperatively, the lymphatic catheter was attached to the su-

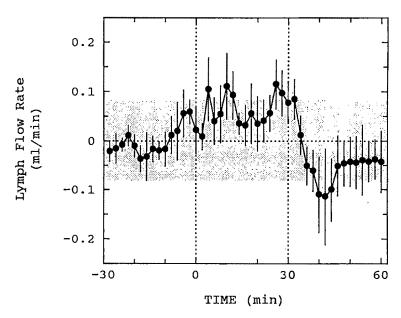

Fig. 2. Fetal left thoracic duct lymph flow rate response to intravenous angiotensin II infusion $(210 \pm 60 \text{ ng/min}, n = 8)$ from 0 to 30 minutes. Data are mean \pm SE change from mean value during 30-minute preinfusion period. Shaded area, 95% Confidence interval around preinfusion

perior vena caval catheter so that lymph spontaneously returned to the circulation. The animals were maintained on a regimen of prophylactic antibiotics for 5 days as previously described,² and experiments were conducted on postsurgical days 5 through 11. This study was approved by the Animal Subjects Committee of the University of California, San Diego, and we followed the guidelines for care and use of laboratory animals as approved by our institution.

Experimental protocol and measurements. The protocol consisted of a 30-minute control period and a 30minute infusion period, followed by a 30-minute recovery period. During the infusion period, either angiotensin II (10 [n = 1], 50 [n = 1], 100 [n = 2], 200 [n = 1], or 400 [n = 3] ng/min) or ANF (500 [n = 2]or 1000 [n = 6] ng/min) was infused into the fetal inferior vena cava in a volume of 0.2 to 0.4 ml/min of isotonic saline solution. At the start of the infusion, 0.8 ml of the infusate was injected into the infusion catheter (volume, 1.2 ml) to reduce the catheter dead space.

Throughout the experiment, fetal arterial and venous pressures, amniotic fluid pressure, heart rate, and left thoracic duct lymph flow rate were measured continuously as previously described.2,9 Fetal vascular pressures were referenced to amniotic fluid pressure,9 and lymph flow was calculated 30 times per second and displayed on a polygraph recorder with an on-line computer.² Data were stored on disk at 30-second intervals with the on-line computer for later data reduction and analyses.

In 12 of the 16 fetuses at 10 and 25 minutes during

the control, infusion, and recovery periods, 1 ml samples of fetal arterial blood were collected for measurement of hematocrit^{10, 11} plasma protein concentration (TS meter, American Optical Corp., Buffalo, N.Y.), and blood gases and pH (model 1302 blood gas analyzer, Instrumentation Laboratory, Inc., Lexington, Mass.). A sample of lymph was collected at the same time for measurement of lymph protein concentration. Changes in fetal blood volume were calculated from hematocrits as previously described. 10,11 This technique is valid because the late-gestation ovine fetus does not have a pool of releasable red blood cells10 such as occurs in the spleen of the adult.

Data analysis. The data are presented as the mean ± SE. Mean values for each variable during the control period were calculated for both groups of animals and compared with an unpaired t test. Because there were no differences between the angiotensin II-and ANF-infused fetuses during the control period, the data were combined. In the figures the data are plotted either as the change from or as a percent of mean control values. Both parametric and nonparametric two-factor analyses of variance for repeated measures were used to determine the statistical significance of the changes with time in each variable. A value of $p \le 0.05$ was assumed to represent statistical significance, but we also present p values from 0.05 to 0.10 because of the potential for dependency of response on infusion rate. If there were statistically significant changes with time ($p \le 0.05$), the 95% confidence interval about the mean control value was plotted as

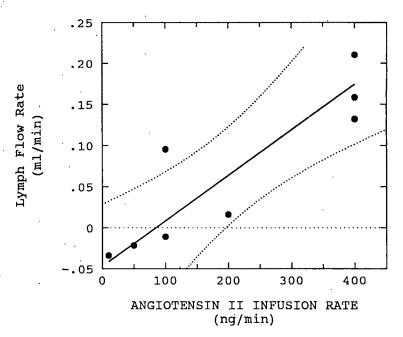

Fig. 3. Thoracic duct lymph flow response in individual fetuses as function of angiotensin II infusion rate (r = 0.888, p = 0.0033). Each *dot* represents mean during last 20 minutes of 30-minute angiotensin II infusion. Regression line and its 95% confidence interval are shown.

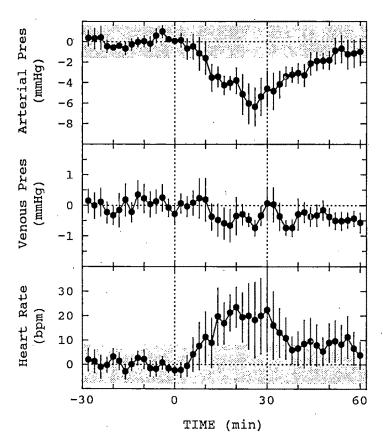

Fig. 4. Fetal arterial pressure, venous pressure, and heart rate responses to intravenous ANF infusion (880 \pm 80 ng/min, n=8) from 0 to 30 minutes. Data are mean \pm SE change from mean value during 30-minute preinfusion period. Shaded area, 95% Confidence interval around preinfusion value.

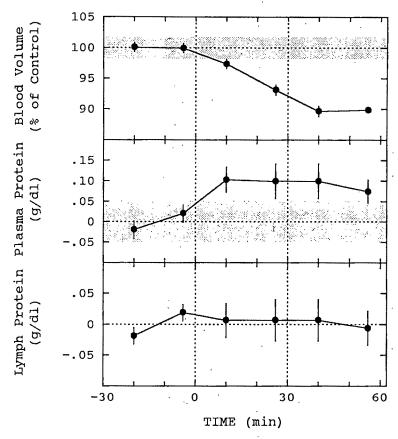

Fig. 5. Fetal blood volume, plasma protein concentration, and lymph protein concentration changes in response to intravenous ANF infusion (880 \pm 80 ng/min, n=8) from 0 to 30 minutes. Data are mean \pm SE relative to value during 30-minute preinfusion period. Shaded area, 95% Confidence interval about mean value during preinfusion period.

 $\pm t_{0.05} \times \sqrt{2 \text{MSE}/n}$, where MSE is the mean square error as determined from the analysis of variance and n is the number of experiments. Bivariate and multivariate regression analysis was used to explore the statistical relationship among variables.

Results

The fetuses averaged 138 days' gestation at the time of experimentation. Mean values during the 30-minute preinfusion period are given in Table I. These values are consistent with previous reports from this laboratory.^{2-1, 10}

Angiotensin II infusion. Angiotensin II was infused at a mean rate of 210 ± 60 ng/min for 30 minutes. As seen in Fig. 1, this produced an elevation in fetal arterial (p < 0.0001) and venous (p = 0.018) pressures during the infusion, with pressures rapidly returning to control levels after the infusion was terminated. The fetal heart rate response to angiotensin II infusion was significant (p < 0.01), two-factor analysis of variance), but this was due to an increase during the recovery period. Heart rate tended to decrease during the low angio-

tensin II infusion rates and increase during the high infusion rates, with no net change occurring during the infusion (Fig. 1). These responses are consistent with the dose-dependent responses to angiotensin II recently reported.¹²

Fetal thoracic duct lymph flow rate tended to increase during the angiotensin II infusion, averaging 20% above control during the last 5 minutes of the infusion (Fig. 2). This increase was dependent on the infusion rate (Fig. 3) in that the lymph flow rate consistently increased only with >100 ng/min of angiotensin II. From multivariate regression analysis, the lymph flow response was dependent on angiotensin II infusion rate (p = 0.0057) and heart rate change (p = 0.032) simultaneously (p = 0.960) but not on the arterial or venous pressure changes. When the angiotensin II infusion was terminated, lymph flow rate decreased rapidly from $18.8\% \pm 10.1\%$ above control to $13.7\% \pm 7.7\%$ below preinfusion levels (p < 0.01).

Fetal arterial pH, carbon dioxide and oxygen tensions, blood volume, and plasma protein concentrations did not change significantly during or after the angio-

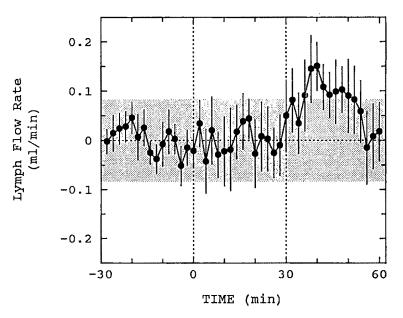

Fig. 6. Fetal left thoracic duct lymph flow rate response to intravenous ANF infusion (880 \pm 80 ng/min, n = 8) from 0 to 30 minutes. Data are mean \pm SE change from mean value during 30-minute preinfusion period. Shaded area, 95% Confidence interval around preinfusion value.

tensin II infusions. Lymph protein concentration underwent a nonsignificant decrease of 0.17 ± 0.07 gm/dl (p = 0.051) by the end of the angiotensin II infusion.

ANF infusion. The fetal cardiovascular responses to 500 to 1000 ng/min of ANF infusion are shown in Fig. 4. Fetal arterial pressure decreased by an average of 6 mm Hg during the infusion (p < 0.001), whereas venous pressure was unchanged and heart rate increased 20 beats/min (p < 0.01). Fetal blood volume decreased (p < 0.0001) in parallel with the fall in arterial pressure (Fig. 5), averaging 10% below normal throughout the recovery period. Plasma protein concentration underwent a small but significant increase (p = 0.0068) of 0.10 ± 0.04 gm/dl during the ANF infusion, whereas lymph protein concentration was unchanged (Fig. 5). Arterial oxygen and carbon dioxide tensions were unchanged during the ANF infusion, whereas pH decreased by 0.016 ± 0.004 units (p = 0.057 parametric, p < 0.05 nonparametric analysis of variance). Oxygen tension increased by 2 mm Hg during the recovery period (p = 0.0011), whereas pH remained reduced.

Even though ANF infusion significantly altered cardiovascular function, fetal left thoracic duct lymph flow rate was not altered during the ANF infusion (Fig. 6). However, with termination of the ANF infusion, lymph flow rapidly increased (p < 0.01) to a maximum of $35.6\% \pm 15.7\%$ above control (Fig. 6). Lymph flow was elevated above control for 20 minutes before returning to basal levels.

Comment

In our study we sought to determine whether the vasoactive hormones angiotensin II and ANF alter lymphatic function in the chronically catheterized ovine fetus. One of the difficulties in studying lymphatic function in the sheep fetus is that lymph flow rate is highly variable on a minute-to-minute basis.² In spite of this, our study provides evidence suggesting that both of these hormones may modulate lymphatic function in the ovine fetus.

During angiotensin II infusion, fetal lymph flow increased. In addition, when the angiotensin II infusion was terminated, fetal lymph flow decreased rapidly in parallel with the falls in arterial and venous pressure. Because these changes in lymph flow occurred independent of blood volume changes, the rise and fall in lymph flow would be consistent with a direct stimulatory effect of angiotensin II on the fetal lymphatic system. Because angiotensin II infusion has been shown to augment thoracic duct lymph flow rate in adult dogs and sheep, 6,7 it appears that the lymph flow response to angiotensin II in late-gestation fetal sheep may be similar to that of the adult.

During ANF infusion, fetal lymph flow rate was unchanged. However, there was a simultaneous decrease in blood volume of approximately 10%. This ANF-mediated decrease in blood volume is independent of renal excretion^{13, 14} and is due to a translocation of fluid from the plasma to the interstitial space; it occurs in both the adult^{13, 14} and fetus.^{15, 16} Because interstitial volume expansion (produced by vascular volume loading)

has been shown to increase fetal thoracic duct lymph flow rate,3 an increase in lymph flow would be expected from the increase in interstitial volume if ANF did not alter fetal lymphatic function. Thus the lack of an increase in lymph flow during the ANF infusion suggests that it suppressed lymphatic flow. This is consistent with a recent report in which ANF reduced the frequency and the amplitude of contractions in lymphatic vessels isolated from lambs.8 In addition, in our study, when the ANF infusion was terminated, there was an elevation in lymph flow rate. Because no volume shifts occurred at this time and because ANF is rapidly cleared from the fetal circulation,15-18 the rise in lymph flow occurred at the time when plasma ANF concentration would be returning to normal. This further supports the idea that ANF suppressed lymphatic function in the ovine fetus. There also may be regional or species differences in the effects of ANF on lymphatic function, in that lymph flow of the dog forelimb was unresponsive to intraarterial ANF infusion.19 However, there were no changes in interstitial volume in the latter study (as determined by weight changes), so that lack of a lymph flow response to ANF in the dog forelimb19 and the present study are not necessarily inconsistent.

In summary, the results of this study suggest that angiotensin II may stimulate and ANF may suppress lymphatic function in the ovine fetus.

Oral-nasal membranes are not the major route for fetal absorption of amniotic fluid arginine vasopressin

William M. Gilbert, MD, Cecilia Y. Cheung, PhD, and Robert A. Brace, PhD San Diego, California

Intraamniotically injected substances such as arginine vasopressin and digoxin have been found to rapidly appear in the ovine fetal circulation, irrespective of whether the fetal esophagus has been ligated or occluded. To determine if the ovine fetal oral-nasal membrane plays a significant role in this fetal absorption of amniotic substances, we used two groups of chronically catheterized fetal sheep with a surgical glove sewed over the fetal head to prevent access of the head to amniotic fluid. In the first group 22.5 μg of arginine vasopressin was injected into the amniotic cavity; in the second group 22.5 μg was injected into the glove over the fetal head. We found that, after injection into the amniotic cavity, there were rapid and highly significant increases in amniotic fluid arginine vasopressin concentrations, from 6.1 \pm 1.3 to 51,249 \pm 18,182 pg/ml (mean \pm SE) (ρ < 0.00001). Concurrently there was a rapid increase in fetal plasma arginine vasopressin concentrations from 4.5 ± 1.3 to 93.8 ± 18.9 pg/ml (p < 0.00001). The increase was significant within 15 minutes and reached a maximum at 60 minutes after the injection. Fetal arterial pressure increased by 10 ± 2 mm Hg, whereas heart rate decreased by 30 \pm 5 beats/min (ρ < 0.00001). In contrast, after the injection into the glove covering the fetal head, there were no significant changes in any of the measured parameters. This suggests that the ovine fetal oral-nasal membrane is not a significant route of absorption of amniotic fluid arginine vasopressin and that the most likely route of absorption is the vascularized fetal surface of the placenta and vascularized fetal membranes, i.e., the intramembranous pathway. (AM J OBSTET GYNECOL 1991;165:1614-20.)

Key words: Vasopressin, amniotic fluid, intramembranous pathway, amnion, chorion

We recently described a pathway, the intramembranous pathway, for the movement of water and arginine vasopressin from the ovine amniotic cavity directly into the fetal circulation within the vascularized fetal membranes and fetal surface of the placenta.1,2 The intramembranous pathway also helped explain the finding of fetal urination being greater than fetal swallowing in many animal and human studies. In fact, we estimated that roughly 200 ml per day of amniotic water would enter the circulation of late-gestation ovine fetuses directly from the amniotic cavity under normal physiologic conditions.1 This intramembranous pathway appears to be the major route for the recirculation of amniotic fluid arginine vasopressin to the fetal circulation, because its absorption was not inhibited by fetal esophageal ligation.2

Digoxin is a naturally occurring plant alkaloid that is used to treat cardiac arrhythmias in adults and fetuses. Hamamoto et al.3 injected digoxin into the amniotic cavity of fetal sheep with an esophageal occluder in place. They found that the digoxin was taken up rapidly by the fetal circulation, with 10 of 11 animals showing higher plasma levels in the descending aorta than in the umbilical vein. This observation conflicts with the expectation that umbilical vein concentrations would be greater than that in the descending aorta if the digoxin were absorbed by the intramembranous pathway, because the latter empties into the umbilical vein. The observation is consistent, however, with that expected if the digoxin were absorbed by the oral-nasal mucosa of the fetus.

In adults the oral and nasal mucosal membranes are highly vascularized and are used as a route of administration of certain medications, including arginine vasopressin and nitroglycerin. In this study we have investigated whether the ovine fetal oral-nasal membranes are a possible route for the absorption of amniotic fluid arginine vasopressin.

Methods

The protocol for this experiment was approved by the Animal Subjects Committee at our institution, and we followed the National Institutes of Health guidelines for the use and care of laboratory animals. Eight timedated pregnant sheep (Nebeker Ranch, Lancaster, Calif.) at a mean (\pm SEM) of 126 \pm 1 days' gestation at the time of surgery were used for this study. The surgical procedures, briefly described here, are detailed elsewhere.4 The animals were anesthetized with 1 gm thiamylal sodium injected intravenously and maintained with halothane (0.5% to 2%) in oxygen by an endotracheal tube. In the supine position, with a sterile surgical field, a midline incision was made in the abdominal wall, and the uterus was exposed through the abdominal incision. The fetal hind limbs were exteriorized through a uterine incision, and bilateral pedal arterial and saphenous venous catheters were placed and advanced to the level of the diaphragm. Amniotic fluid catheters were sutured to each hind leg. The fetal legs were returned to the uterus, and fetal amnion and chorion were ligated around the catheters twice to prevent any leakage of amniotic fluid. The uterus was closed in a water-tight fashion with a continuous suture.

The fetal head was then brought out through a second incision. A size 8 surgical glove was placed over the fetal head and sutured in a purse-string fashion to the base of the neck with a continuous suture loosely placed through the glove and skin of the neck. Size 8 was selected because it fit loosely over the head. One finger of the glove was cut and a catheter was placed into the area of the nose and ligated in place, thereby sealing the hole in the glove. The head was placed back into the uterus, and the fetal membranes and uterus were closed in a water-tight manner as described above. Maternal femoral arterial and venous catheters were placed in the right groin and advanced to the level of the maternal diaphragm. All maternal and fetal catheters were tunneled subcutaneously into a pouch sewn on the flank of the ewe.

The vascular catheters were flushed daily with heparin sodium (1000 U/ml) to maintain patency. Antibiotics (1 gm ampicillin [Omnipen, Wyeth Laboratories, Philadelphia]) were instilled daily into the amniotic cavity and intramuscularly (800,000 U of penicillin G and 1 gm dihydrostreptomycin) to the ewe during the postoperative preexperimental period.

Experiments were begun at least 5 days after surgery. The fetuses were monitored continuously for heart rate and arterial, venous, and amniotic fluid pressures. After a stable 30-minute control period, 18 ml of warmed saline solution containing 22.5 µg of arginine vasopressin was injected into the amniotic cavity of four fetuses. The injection catheter was flushed with 50 ml of amniotic fluid, and the injected arginine vasopressin was thoroughly mixed with repeated withdrawals and reinjections of amniotic fluid. In a second group of four fetuses, 18 ml of warmed normal saline solution containing 22.5 µg of arginine vasopressin was injected into the catheter that was sewn into the glove over the fetal head, followed by 5 ml of normal saline solution. In one animal from each group the opposite protocol (glove or amniotic fluid injection) was performed on the animal 4 days later. Fetal and maternal arterial plasma and amniotic fluid were sampled at 10 and 20 minutes during the 30-minute control period and at 15, 30, and 60 minutes after the injection of arginine vasopressin. A 2 ml sample of the injection solution from both groups was assayed for arginine vasopressin concentration. Fetal arterial blood (from the descending aorta) was sampled for blood gases and pH (Instrumentation Laboratory [Lexington, Mass.] model 1302 blood gas analyzer); sodium, chloride, and potassium ion concentrations (Nova Model 5 + 5 electrolyte analyzer, Waltham, Mass.); osmolality (freezing point depression, Advanced Instruments Inc., Needham Heights, Mass.); hematocrit; and plasma concentration of arginine vasopressin. Maternal blood and amniotic fluid were sampled for electrolytes and osmolality at the same times as stated above. The amniotic fluid volume was estimated in the intraamniotically injected group by dividing the amount of arginine vasopressin injected by the mean amniotic arginine vasopressin concentration during the 1 hour after the injection.

Radioimmunoassay. Plasma and amniotic samples were extracted with C₁₈ microcolumns (Sep-Pak, Waters Associates, Milford, Mass.), and arginine vasopressin concentrations were measured by radioimmunoassay with an antiserum generously provided by Dr. Ben U (University of California, San Diego) and tracer obtained from New England Nuclear (Boston), as previously described.5 Extraction recovery averaged $84\% \pm 3\%$, and sensitivity was 0.2 pg per tube. The intraassay and interassay coefficients of variation were 6% and 14%, respectively.

Statistical analysis. The data are presented as the mean ± SE. Changes with time in a single variable were analyzed with a two-factor repeated-measures analysis of variance, with time and animal being the two factors. All parameters from the control period of each group were compared with group t tests. All arginine vasopressin concentrations (plasma and amniotic fluid samples) were log transformed before analysis to correct for skewness of data. To determine whether changes in time in one variable were significantly different when the two groups of animals were compared, a threefactor repeated-measures analysis of variance was used, with time, treatment, and animal being the factors. Statistical significance was accepted at $p \le 0.05$, and changes referred to as significant are at this level unless specified otherwise.

At the end of the experiments, the animal was killed

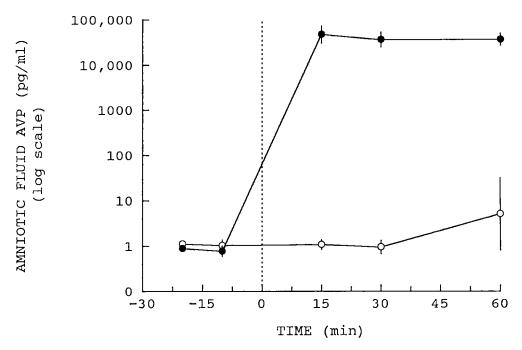

Fig. 1. Mean (±SEM) amniotic fluid arginine vasopressin concentrations (log scale) after injection of 22.5 µg arginine vasopressin (dotted vertical line) into amniotic cavity (closed circles) or gloved fetal head (open circles). Changes from control period are highly significant (p < 0.00001) for intraamniotically injected group, but no significant change occurred in glove-injected animals.

Table I. Mean (±SE) control values before arginine vasopressin injection*

	Site of injection of 22.5 µg of arginine vasopressin				
Variable	Amniotic fluid	Glove			
Fetus		-			
Gestational age (days)	132 ± 2	130 ± 1			
Arterial pH	7.33 ± 0.01	7.32 ± 0.01			
Pco ₂ (mm Hg)	55.8 ± 1.4	55.5 ± 0.6			
Po ₂ (mm Hg)	19.0 ± 1.6	21.0 ± 0.8			
Hematocrit (%)	34.2 ± 2.0	36.7 ± 2.7			
Weight (kg)	3.5 ± 0.2	3.0 ± 0.4			
Vasopressin (pg/ml)					
Fetal plasma	4.5 ± 1.3	5.5 ± 1.3			
Amniotic fluid	6.1 ± 0.9	7.6 ± 1.5			
Maternal plasma	1.5 ± 0.2	1.2 ± 0.04			

^{*}In each group n = 5 animals except n = 4 in arginine vasopressin measurements in glove-injected group. There were no statistical differences between groups in the abovemeasured parameters.

with pentobarbital sodium (300 mg/kg), an autopsy was performed on the fetus, and fetal weight was recorded.

Results

Mean values during the control period for the two groups of animals are shown in Table I. No statistically significant differences were found between either group, and these control values are consistent with those values found previously in our laboratory. Fig. 1

shows the arginine vasopressin concentrations in the amniotic fluid before and after the injection of 22.5 µg arginine vasopressin into either the amniotic cavity or the glove covering the fetal head. Amniotic fluid concentrations increased sharply after injection of arginine vasopressin into the amniotic cavity, and the concentration remained elevated for the duration of the experiment. Although the changes with time in concentrations were highly significant (p < 0.00001) for the intraamniotically injected group, there was no significant change over time in the amniotic fluid concentration when the arginine vasopressin was injected into the glove over the fetal head. However, in the latter group there was a nonsignificant increase in the amniotic fluid arginine vasopressin concentration at 60 minutes after the injection, as a result of a rise in one animal.

The fetal plasma arginine vasopressin concentrations are presented in Fig. 2. Significant increases (p < 0.00001) were observed in the amniotically injected group within 15 minutes, and a maximal level was reached within 60 minutes. There were small increases over time in fetal plasma arginine vasopressin concentrations after injection into the glove, but this did not reach statistical significance. This increase in the gloved group was on average 6.8% of that which occurred after intraamniotic injection. In several animals in both groups, fetal plasma arginine vasopressin samples were taken 2 hours after the injection. In the

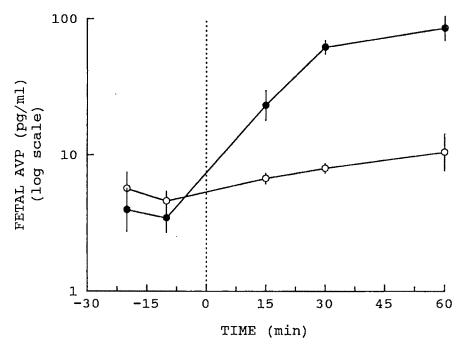

Fig. 2. Mean (±SEM) fetal arterial plasma arginine vasopressin concentration (log scale) after injection of 22.5 µg arginine vasopressin (dotted vertical line) into amniotic cavity (closed circles) or gloved head (open circles). Intraamniotic group had significant increases within 15 minutes when compared with both control period and glove-injected group (p < 0.00001). There were no significant changes in glove-injected group over time.

amniotically injected group, the concentration did not change from the 1-hour postinjection value. In the intraglove-injected group, there was a further nonsignificant increase in arginine vasopressin concentration. In one animal in the gloved group, 22.5 µg was injected into the amniotic cavity 1 hour after the injection into the glove over the fetal head. In that animal there were large increases in amniotic fluid and fetal plasma arginine vasopressin concentrations and arterial pressure and decreases in heart rate.

Fig. 3 shows the changes in fetal arterial pressure and heart rate after the injection of arginine vasopressin. Significant increases in arterial pressure of 10 \pm 2 mm Hg (p < 0.00001) and decreases in heart rate of 30 ± 5 beats/min occurred in the intraamniotically injected group. These increases in the arterial pressure occurred within 15 minutes after the intraamniotic injection, with significant decreases in heart rate by 20 minutes after the injection. These physiologic changes in arterial pressure and heart rate coincide with the measured increase in fetal plasma arginine vasopressin concentrations (Fig. 2). There were no significant changes in either arterial pressure or heart rate in the group with the arginine vasopressin injected into the glove over the fetal head. There were no significant changes in either the venous pressure or the amniotic pressure after the injections in either group.

There were no changes over time in either group

with respect to fetal pH, Pco₂, Po₂, plasma osmolality, or electrolyte concentrations. Likewise, there were no differences between groups over time with respect to amniotic fluid osmolality (during control period, 286 ± 8 mOsm/kg for amniotic fluid-injected group and 292 ± 5 mOsm/kg for the glove-injected group). The maternal plasma osmolalities (during control period 303 ± 4 mOsm/kg for the amniotic fluid-injected group and 304 ± 2 mOsm/kg for the glove-injected group) were different neither over time nor between groups. The maternal arginine vasopressin concentrations did not change significantly over time and averaged 2.2 ± 0.6 pg/ml for the amniotic fluid-injected group and 1.6 ± 0.5 pg/ml for the glove-injected group after the injection.

The amniotic fluid volume in the intraamniotically injected group was calculated to be 569 ± 143 ml (range, 174 to 933 ml). This value is consistent with volumes determined previously in our laboratory.

At autopsy, the surgical glove remained sutured over the fetal head, and the catheter was in place within the glove in all animals. The glove was neither overly distended nor collapsed but contained a modest amount of fluid.

Comment

In this study we found minimal absorption of arginine vasopressin into the fetal circulation when it was

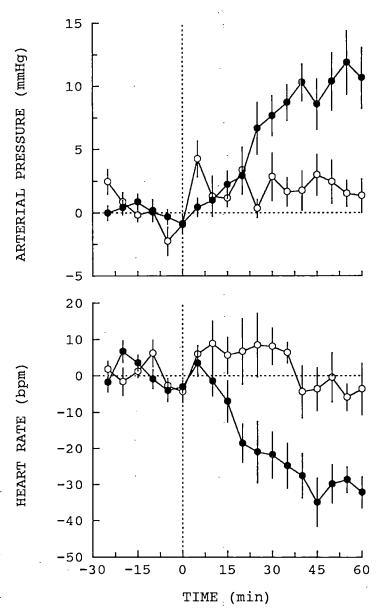

Fig. 3. Mean (\pm SEM) change from control in fetal arterial pressure (*upper*) and heart rate (*lower*) after injection of 22.5 µg arginine vasopressin (*dotted vertical line*) into amniotic cavity (*closed circles*) and gloved head (*open circles*). Arterial pressure increased significantly in intraamniotically injected group (p < 0.00001) but was unchanged in glove-injected group. Fetal heart rate decreased significantly in intraamniotically injected group (p < 0.00001) and was unchanged in glove-injected group.

injected into a glove covering the fetal head. Conversely, we found a rapid and significant absorption into the fetal circulation when it was injected into the amniotic cavity when a glove covered the fetal head. From this we conclude that the fetal oral-nasal membranes are not a significant route for the absorption of amniotic fluid arginine vasopressin relative to that which occurs across the fetal surface of the placenta and the vascularized fetal membranes (i.e., the intramembranous pathway). We did find, however, a small

increase in fetal plasma arginine vasopressin concentrations in three of four animals when it was injected into the glove covering the fetal head. This increase in concentration was minor (6.8%) when compared with the amount absorbed through the intramembranous pathway. This increase would suggest that a small amount of arginine vasopressin may be absorbed by the oral-nasal membranes or fetal swallowing.

In adult humans the nose is highly vascularized and is used to administer certain medications such as vasopressin in patients with diabetes insipidus. Furthermore, sublingual nitroglycerin is rapidly absorbed in subjects with cardiovascular disease. Thus, in spite of the presence of this route of absorption in the adult, it would appear that the fetal oral-nasal membranes are not a major route for absorption in utero relative to the absorption that occurs through the intramembranous pathway.

Another point to strengthen this conclusion is that we injected 22.5 µg of arginine vasopressin into a closed space over the fetal head in one of the groups of fetuses. Thus arginine vasopressin concentrations within the glove would be very high because of the small volume of distribution. In the second group we injected 22.5 µg of arginine vasopressin into the amniotic cavity, which has a much larger volume of distribution. Therefore the fetal oral-nasal membranes most likely were exposed to a much higher concentration than was the intramembranous pathway. This difference in concentrations strengthens our conclusion that oral-nasal absorption of arginine vasopressin appears small compared with intramembranous absorption.

In our prior study² we injected 1 to 25 µg of arginine vasopressin into the amniotic cavity and found that the absorbed arginine vasopressin was physiologically active. In this study we found similar results, in that there was a rapid absorption of physiologically active arginine vasopressin as manifested by an increase in arterial pressure and a fall in heart rate (Fig. 3). Ervin et al.6 had previously injected 25 µg of arginine vasopressin into the ovine amniotic cavity and found that the fetal plasma concentrations had increased within 30 minutes. They found that this increase, which they felt was due to fetal swallowing, did not significantly change any physiologic variable such as heart rate or arterial pressure. Our study demonstrated that the arginine vasopressin absorbed into the fetal circulation was not absorbed primarily by fetal swallowing. Near the end of the study, in the glove-injected group there was a nonsignificant increase in amniotic fluid and fetal plasma arginine vasopressin concentrations. This may indicate a small amount of absorption by the oral-nasal pathway, absorption by fetal swallowing, or spillage of arginine vasopressin from the neck of the glove into the amniotic cavity with subsequent intramembranous absorption. However, this absorption was minimal compared with the absorption after intraamniotic injection. Since neither fetal swallowing nor the oral-nasal membranes appear to be a major pathway for the absorption of amniotic fluid arginine vasopressin, the only remaining route for its movement into the fetal circulation is the intramembranous pathway.

Although this study confirms our previous stud-

ies,1,2 we are unable to explain the finding of Hamamoto et al.8 of a higher level of digoxin in the descending aorta when compared with that in the umbilical vein. A possible explanation is that the fetal oral-nasal membranes may absorb digoxin but not arginine vasopressin much more rapidly than does the intramembranous pathway. This difference cannot be resolved until the absorption of intraamniotic digoxin in fetuses is studied in more detail.

It may be suggested that a method to evaluate the extent of arginine vasopressin absorption by the intramembranous pathway would be to examine the umbilical arterial-venous differences. There are at least three potential problems with this idea. One is that arginine vasopressin is cleared by the placenta.7 The second is that the umbilical blood flow rate is large, with a flow of 200 ml/min/kg fetal body weight.8 In our fetuses (3.25 kg) umbilical blood flow would equal 650 ml/min through the umbilical vein. The third is that only a moderate to large arginine vasopressin concentration difference could be detected because of inherent assay variability in combination with the high umbilical blood flow rate plus the placental metabolism of arginine vasopressin. Thus, because fetal plasma arginine vasopressin concentrations increased only slowly over 1 hour, an arterial-venous concentration difference would most likely not be detectable in the present study.

At autopsy we found that the glove over the fetal head contained a modest amount of fluid. Previously, in a group of ovine fetuses who had both the trachea and the esophagus ligated we found that a glove sutured in place over the fetal head was distended with thick, tenacious secretions at autopsy.9 Thus this study would imply that the fetus continued to swallow its oral and lung secretions in spite of the glove over the its head. Whether the glove affected breathing movements is unknown.

In summary, this study shows that intraamniotically injected arginine vasopressin is rapidly absorbed by the fetal blood that perfuses the fetal surface of the placenta and the fetal blood perfusing the membranes. We would speculate that this intramembranous pathway may provide an avenue by which we can treat fetal disease by administering medications such as digoxin into the amniotic cavity to treat fetal cardiac arrhythmias or antibiotics to treat fetal infections.

We thank R. Scot Payne and Tamara Tetzke for their assistance with this study.

Amniotic fluid volume response to esophageal occlusion in fetal sheep

Yuji Fujino, MD, Connie L. Agnew, MD, Peter Schreyer, MD, M. Gore Ervin, PhD, Dan J. Sherman, MD, and Michael G. Ross, MD

Torrance, California

Although ovine and human fetuses swallow considerable volumes of fluid, the impact of absence of fetal swallowing on amniotic fluid volume regulation is unclear. To study the role of fetal swallowing on urine production and amniotic fluid, seven ovine fetuses (126 ± 1 days) were chronically prepared with fetal biadder and vascular catheters, an esophageal flow probe, an inflatable esophageal cuff, and amniotic fluid catheters. In the five fetuses that underwent esophageal ligation after the control period, fetal swallowing averaged 0.27 ml/min before occlusion. In response to esophageal occlusion, significant increases were noted in fetal plasma arginine vasopressin (6.9 ± 2.6 to 16.6 ± 4.4 pg/ml) and urine osmolality (159 ± 1 to 324 ± 30 mOsm/kg), whereas urine volume (0.25 ml/min) did not change. Amniotic fluid volume increased nearly threefold after 3 days of esophageal occlusion (582 ± 180 to 1530 ± 271 ml). Amniotic fluid volume remained normal (334 to 419 ml) in the one fetus in which the occluder did not inflate. In the one fetus in which the esophagus was occluded at surgery, amniotic fluid volume was increased after the surgical recovery period (1489 ml). These data indicate an important role of fetal swallowing in amniotic fluid homeostasis and the potential interaction of swallowing with fetal urine production. (Am J Obster Gynecol. 1991;165:1620-6.)

Key words: Ovine fetus, fluid balance, polyhydramnios

Amniotic fluid volume homeostasis results from a balance of fetal fluid secretion and resorption. In the near-term ovine pregnancy, fetal urine contributes from 400 to 1200 ml per day to the amniotic or allantoic cavities. Although the fetal lung produces 200 to 400 ml of fluid per day, a major portion of ovine fetal lung

fluid is swallowed.^{2,3} In addition to ingested lung fluid, ovine and human fetuses may swallow up to 1000 ml of amniotic fluid per day.^{2,4-7} Amniotic fluid water and electrolytes also may be exchanged by an intramembranous route to the fetus (across the amniotic membranes through intramembrane vessels⁸) or a transmembranous route to the mother.⁹

Congenital anomalies that impair or prevent human fetal swallowing (anencephaly, esophageal atresia, myotonic dystrophies) are frequently associated with polyhydramnios, confirming a role of swallowing in amniotic fluid regulation.¹⁰ However, polyhydramnios does not invariably develop in these pregnancies.¹¹

imal models. Esophageal ligation of the fetal rhesus monkey resulted in transient polyhydramnios, with amniotic fluid volume returning to normal within 2 weeks.12 In studies of the ovine fetus amniotic fluid volumes 3 weeks after acute surgical esophageal ligation were not different from control values.13 The authors concluded that deglutition is not necessary for the regulation of amniotic fluid volume in sheep.13 However, acute effects of esophageal ligation were not examined, nor was fetal urine or lung fluid production measured to determine if compensatory adaptations occurred. Similarly, the acute urinary effects of esophageal ligation have not been examined, although Smith et al.14 reported normal fetal urinary volume and osmolality after recovery from surgical ligation of the esophagus.

In this study we evaluated the effects of esophageal occlusion on fetal urine production and amniotic fluid volume.

Material and methods

Animals and surgery. Seven Western crossbred pregnant sheep with singleton fetuses were studied at a mean gestational age of 126 ± 1 day. Guidelines approved by Harbor-University of California Los Angeles Medical Center for the care and use of animals were followed. Animals were housed indoors in individual steel study cages and maintained under a controlled 12-hour-light/12-hour-dark lighting regimen. Both food and water were available at will, except for the withholding of food during the 24-hour period immediately before surgery.

Anesthesia for surgery was induced by an intramuscular injection of ketamine hydrochloride (20 mg/kg) plus atropine sulfate (30 µg/kg) and subsequently maintained by a continuous intravenous infusion of ketamine (15 mg/kg/hour). The uterus was exposed by a midline abdominal incision, and a small hysterotomy was performed to provide access to a single fetal hind limb. Polyethylene catheters (1.0 mm inner diameter, 1.8 mm outer diameter) were placed in the fetal dorsal hind limb vein and artery and threaded to the inferior vena cava and abdominal aorta, respectively. Before hysterotomy closure, a plastic catheter was sutured to the distal tip of the hind limb and a second catheter was placed adjacent to the fetal head to provide access to the amniotic cavity. The hind limb was returned into the uterus, and the hysterotomy was closed in two layers.

A second hysterotomy was performed, and a polyethylene catheter was placed in the fetal bladder by cystotomy. Through a third hysterotomy the fetal left hemithorax was entered through the eighth intercostal space. The peritoneum overlying the esophagus was incised for a distance of 3 cm cephalad to the diaphragm.

An inflatable occluder (In Vivo Metric Systems, Healdburg, Calif.) was placed on the thoracic esophagus, and an ultrasonographic flow probe (Transonic System Inc., Ithaca, N.Y.) was placed around the esophagus, caudal to the occluder. The fetal chest was closed in layers, the uterine and maternal incisions were repaired, and catheters were externally accessed through a maternal flank incision. Catheters also were placed in the maternal inferior vena cava and abdominal aorta through the femoral vein and artery in one leg.

Fetal vascular catheters were maintained patent by filling the catheter dead space (I ml) with heparin sodium (1000 U/ml); catheters were sealed with sterile plastic caps. Maternal vascular catheters were filled with heparinized saline solution (10 U/ml), and both fetal and maternal catheters were flushed daily with heparinized saline solution (10 U/ml).

All animals were allowed a minimum of 5 days for postoperative recovery, during which time the fetuses received intravenous infusions of oxacillin (33 mg) and gentamicin sulfate (8 mg) twice daily for 2 days. Oxacillin (967 mg), chloramphenicol (500 mg), and gentamicin sulfate (72 mg) also were administered into the maternal vein.

Study design. The study design consisted of 4 days of fetal assessment. On each of the study days fetal urine production, esophageal flow, and fetal and maternal arterial blood pressures and amniotic fluid pressure were monitored. Amniotic fluid volume determinations were performed on days 1 and 4.

Study day 1 was performed as follows: The fetal bladder catheter was opened to gravity and drained during a 1-hour equilibration period. Beginning at time 0, fetal urine flow was collected at 15-minute intervals during a 1-hour control period (time 0 to 1 hour) while fetal esophageal flow was measured continuously. At time 30 minutes and 1 hour, fetal, maternal, and amniotic fluid pressures were measured, and fetal and maternal arterial blood samples (4 ml) were withdrawn. Fetal blood samples were replaced with an equivalent volume of maternal blood drawn before the study, and maternal blood samples were replaced with an equivalent volume of 0.9% saline solution. Hematocrit, pH, PO2, Pco₂, plasma osmolality, and sodium, chloride, potassium, and arginine vasopressin concentrations were measured.

At time 1 hour, amniotic fluid aliquots (1 ml) were obtained for background counts and technetium 99labeled maternal red blood cells were injected into the amniotic fluid. Amniotic fluid was mixed by gentle shaking of the maternal abdomen with an external sling.15 Amniotic fluid samples were withdrawn from both amniotic catheters for 6 hours (at time 2 hours and from time 3 to 7 hours at 30-minute intervals). Fetal urine production was monitored for an additional 2 hours after the injection of ⁹⁹Tc-labeled red blood cells and urine volume, osmolality, and electrolytes were measured. All fetal urine samples were returned to the amniotic cavity at hourly intervals. Fetal swallowing was measured for 7 hours (time 0 to 7 hours). Repeat fetal and maternal blood samples were drawn at time 3 and 7 hours.

At time 7 hours of study day 1, the fetal esophagus was occluded with the inflatable occluder, and the absence of flow was confirmed with the flowmeter.

On study days 2 and 3, after a 1-hour equilibration period, fetal urine was drained into sterile tubes for 1 hour. The esophageal occluder was emptied of fluid and reinflated each morning to assure full inflation. Esophageal flow was monitored to confirm the absence of flow. Fetal and maternal blood samples were withdrawn at time 0 and 1 hour.

Study day 4 was identical to day 1 with the exception that the esophagus remained occluded for the duration of the study.

Analytic methods

Measurements of amniotic fluid volume. The volume of amniotic fluid was measured with ^{99}Tc -labeled red blood cells. Maternal red blood cells were labeled with a kit (Cameda Medical Products Inc., Md.) modified by the addition of 0.6 ml of 0.1% sodium hypochlorite. After the ^{99}TC (400 μCi) addition, an aliquot of the maternal red blood cell solution was counted and the injected dose calculated by weighing the syringe before and after injection.

Amniotic fluid samples were counted for ⁹⁹Tc on a 1282 Compugamma γ-counter (LKB Wallac, Turku, Finland) incorporating a 6-hour half-life correction. Amniotic fluid volume was calculated by extrapolation to time 0 of the semilogarithmic regression line of the average ⁹⁹Tc counts (withdrawn from both amniotic catheters) versus time, as described previously.^{7, 15}

Maternal and fetal blood pressures and heart rate were monitored with a Beckman R-612 physiologic recorder (Beckman, Palo Alto, Calif.) and Statham P-23 transducers. Mean fetal blood pressure was corrected for amniotic fluid pressure. Maternal and fetal blood pH, PO₂, and PCO₂ values were determined at 39° C with a Radiometer BMS2 MK2 acid-base analyzer system (Radiometer CO., Copenhagen). Plasma osmolality was measured by freezing point depression on an advanced digimatic osmometer (Model 3MO, Advanced Instruments, Needham Heights, Mass.). Plasma, urine, and amniotic fluid electrolyte levels were determined by a NOVA5 electrolyte analyzer (NOVA Biochemical, Waltham, Mass.). Plasma arginine vasopressin levels were measured by radioimmunoassay of plasma (1 ml) extracted on Sep-Pak columns (Waters Associates, Milford, Mass.), as previously described from our laboratory.16

Fetal volume swallowed was calculated as positive flow minus negative flow with a transit-time ultrason-ographic flowmeter and computer analysis, as previously described from our laboratory. ^{5, 6} The data are presented as volume swallowed per unit time.

Urinary sodium excretion was expressed as the product of the urine sodium concentration and urine volume. Urinary potassium, chloride, and osmolar excretions were calculated in the same manner. Renal osmolar clearance (Cosm) was calculated as Cosm (ml/min) = (UosmV)/Posm, where UosmV is urinary osmolar excretion and Posm is plasma osmolality. Renal free water clearance (CH₂O) was calculated as the difference between the urine volume and the renal osmolar clearance: $CH_2O = Uvol - Cosm$.

Statistics and data analysis. All values are expressed as the mean \pm SEM. Mean values for study periods (before and after ⁹⁹Tc-labeled red blood cells injection) and study days were determined. Differences between study periods were assessed by repeated-measures analysis of variance with trends in the data considered statistically significant when the F test yielded a p < 0.05. Comparisons of the control values to the study periods were determined with Dunnett's test (p < 0.05). Linear and polynomial regression were used to evaluate the relationship of fetal plasma arginine vasopressin and blood pressure and urinary parameters. Differences between amniotic fluid values were determined by paired t test.

Results

Five of the seven animals surgically prepared completed the study as intended. The results are presented for these five fetuses. In one fetus the esophageal occluder did not inflate and in one fetus the esophagus was inadvertently occluded at the time of surgery. The amniotic fluid volume responses in these two fetuses are presented for comparison.

Fetal arterial values. There was no significant change in fetal arterial pH, PCO_2 , hematocrit, heart rate, plasma osmolality, or electrolyte composition in response to esophageal occlusion. There was a near-significant trend toward a decrease in fetal arterial PO_2 during the study (p=0.057) (Table I). Fetal mean blood pressure (43 ± 2 to 46 ± 3 mm Hg), plasma potassium level (3.9 ± 0.1 to 4.5 ± 0.1 mEq/L), and plasma arginine vasopressin level (6.9 ± 2.6 to 16.6 ± 4.4 pg/ml) increased significantly on study day 4 (Table I, Fig. 1). Fetal plasma arginine vasopressin level was significantly correlated with changes in fetal blood pressure (p=0.009, p=0.602).

Maternal arterial values. Maternal pH (7.46 ± 0.02) , Po₂ $(86.1 \pm 0.8 \text{ mm Hg})$, Pco₂ $(32.1 \pm 3.0 \text{ mm Hg})$, hematocrit $(31.5\% \pm 1.6\%)$, mean blood pressure $(95 \pm 6 \text{ mm Hg})$, heart rate $(125 \pm 4 \text{ beats/min})$,

				, 1 0

Blood pressure (mean, mm Hg)	43 ± 2	43 ± 2	42 ± 2	44 ± 2	47 ± 3*	46 ± 3*
Heart rate (beats/min)	172 ± 3	170 ± 4	175 ± 3	171 ± 5	172 ± 8	174 ± 10
Osmolality (mOsm/kg)	293 ± 2	292 ± 3	293 ± 3	294 ± 3	292 ± 3	295 ± 3
Sodium (mEq/L)	142.7 ± 0.4	142.9 ± 0.5	143.1 ± 0.1	143.9 ± 1.3	143.8 ± 2.0	143.2 ± 1.3
Potassium (mEq/L)	3.9 ± 0.1	3.9 ± 0.1	4.1 ± 0.1	$4.3 \pm 0.1*$	$4.5 \pm 0.2*$	4.5 ± 0.1 *
Chloride (mEq/L)	110.9 ± 1.3	111.0 ± 1.1	110.3 ± 0.6	109.2 ± 0.6	109.1 ± 1.7	108.8 ± 1.2

Table I. Fetal arterial values before (day 1) and after (days 2, 3, and 4) exophageal occlusion

plasma osmolality (298 ± 2 mOsm/kg), and plasma arginine vasopressin (6.1 \pm 2.7 pg/ml), sodium $(149.9 \pm 0.6 \text{ mEq/L})$, potassium $(4.3 \pm 0.2 \text{ mEq/L})$, or chloride (112.9 \pm 0.6 mEq/L) concentrations did not change.

Fetal urine values. Fetal urine volume did not change from basal values of 0.25 ± 0.04 ml/min during the study (Fig. 1). However, fetal urine sodium, potassium, and chloride concentrations and osmolality significantly increased in response to esophageal occlusion (Table II, Fig. 1). Consequently, urinary sodium, potassium, chloride, and osmolar excretions significantly increased and free water clearance decreased. Fetal urinary osmolar excretion (p = 0.04, r = 0.514) and osmolar clearance (p = 0.022, r = 0.553) were significantly correlated with fetal plasma arginine vasopressin level. However, there was not a significant correlation of free water clearance and arginine vasopressin level (p = 0.068, r = 0.475).

Fetal swallowing and amniotic fluid. Fetal swallowing averaged 0.27 ± 0.07 ml/min before esophageal occlusion. Basal amniotic fluid volume (582 ± 180 ml) significantly increased on study day 4 after esophageal occlusion (1530 \pm 271 ml) (Fig. 1). There were no changes in amniotic fluid osmolality or electrolyte composition (Table III).

In the fetus in which the esophageal occluder did not inflate, amniotic fluid volume was 334 ml on study day 1 and 419 ml on study day 4. Fetal swallowing averaged 0.16 and 0.25 ml/min, respectively. In the fetus in which the esophagus was occluded at surgery, esophageal flow was not detected during the study. Amniotic fluid volumes on day 1 and 4 were 1489 and 1530 ml, respectively.

Comment

In all fetuses in this study normal physiologic parameters were demonstrated during the control period before esophageal occlusion. Mean basal fetal urine osmolality (159 mOsm/kg), a sensitive index of fetal stress, was in the normal range for fetuses of this gestational age. In spite of the normal urine osmolality, the basal urine production rate (0.1 ml/kg/min) was below previously reported values from our laboratory and others.17-19 Notably, Daniel et al.20 have demonstrated a wice range of normal fetal urine flow rates (0.1 to 0.4 ml/kg/min) with urine osmolalities <200 mOsm/kg. Similarly, Gresham et al.1 noted "large interindividual differences in urine flow (0.09 to 0.31 mg/kg/min) with urine osmolalities <160 mOsm/kg. Thus biologic variability may have contributed in part to the low Lrine production rates in our study. Numerous other factors, including atrial natriuretic factor, catecholamines, and aldosterone, may alter fetal urine production or composition. Basal fetal urinary sodium concentration was 25% to 40% less than that noted in previous studies by our laboratory and others. 17-19 Although fetal plasma atrial natriuretic factor and maternal-fetal aldosterone were not measured in our study, it also is possible that alterations in these values contributed to the reduced urine volume.

Amniotic fluid volume (582 ml) and osmolality (275 ± 3 mOsm/kg) during the control period were consistent with previous determinations.7, 15, 15, 21 Thus there was no indication that the surgical preparation influenced basal amniotic fluid volume. Fetal volume swallowed before esophageal occlusion (0.27 ml/min) extrapolated to 392 ml/day, a volume similar to the extrapolated daily urine volume.

In response to esophageal occlusion, fetal plasma arginine vasopressin and urine osmolality significantly increased, although urine flow rates did not change. With the exception of a slight increase in plasma potassium, there were not statistically significant changes in fetal arterial values on days 2 or 3. Although fetal plasma arginine vasopressin was not statistically greater than basal levels until day 4, plasma arginine vasopressin levels similar to those observed on days 2 and 3 may

^{*}p < 0.05, versus day 1 control.

induce production of hypertonic urine in fetuses >110 days' gestation.²² Increased fetal plasma arginine vasopressin generally is associated with a reduced urinary flow rate.²⁰ However, Daniel et al.²⁰ demonstrated significant increases in fetal urine osmolality with minimal volume changes at lower levels of urine flow rates. Thus the maintenance of urinary flow rates and the lack of a statistically significant correlation between plasma arginine vasopressin and fetal urinary free water clearance suggests that esophageal occlusion affected other regulatory factors in addition to arginine vasopressin.

Fetal mean arterial blood pressure significantly increased on study day 4 in association with plasma arginine vasopressin levels of 16 pg/ml. Although Tomita et al. ²² demonstrated no increase in fetal arterial blood pressure with a 6.5 \pm 3.9 pg/ml increase in plasma arginine vasopressin, Wiriyathian et al. ²³ demonstrated increased fetal mean arterial pressure at plasma arginine vasopressin levels of 8 to 9 μ U/ml (18 to 20 pg/ml). In the present study, the significant correlation between fetal plasma arginine vasopressin and arterial blood pressure suggests that the elevated plasma levels noted on day 4 contributed to the increased fetal blood pressure.

The increase in plasma arginine vasopressin suggests that the fetus attempted to conserve water that was no longer available by gastrointestinal resorption. Although the mechanism for the increased levels is uncertain, it may have contributed to the maintenance of normal fetal plasma osmolality and hematocrit. There were no acute blood pressure or heart rate changes indicative of aortic constriction or cardiovascular compromise. Although fetal venous and lymphatic pressures were not determined, it appears that baroreceptor responses did not contribute to increased arginine vasopressin secretion. Notably, the occluder was placed between the esophagus and the vagus nerve, so as not to alter vagal innervation. Compression of the esophagus and potential esophageal distention (with fluid sequestration proximal to the occluder) may have induced a nonspecific fetal arginine vasopressin stress response. Although not statistically significant, the tendency toward reduced fetal arterial Po2 also may have potentiated arginine vasopressin stimulation.24 Neither Wintour et al.18 nor Smith et al.14 reported plasma arginine vasopressin levels after acute surgical ligation. However, Smith et al.14 reported urinary osmolality/plasma osmolality ratios of 0.42 to 0.69 at 5 days after surgery, suggesting the absence of an arginine vasopressin response. Nevertheless, the lack of measurements during the initial 4 days after esophageal occlusion limits comparisons to the acute effects of esophageal occlusion in the present study.

Amniotic fluid volume increased nearly threefold after esophageal occlusion. In sheep, amniotic fluid is produced by fetal urine production and lung liquid that is not swallowed. Amniotic fluid resorption occurs by fetal swallowing and perhaps transmembraneous or intramembranous flow.8 After esophageal occlusion in the present study, fetal urine production continued at an equivalent rate, presumably contributing to amniotic fluid volume. Although within normal limits (as discussed above), the relatively low rates of urine flow throughout the study likely would have moderated the increase in amniotic fluid volume. Nevertheless, continued urine production indicates that fetal swallowing and urine flow rates may not be coupled under pathologic conditions. Fetal lung fluid, although not measured, was likely secreted into the amniotic cavity rather than swallowed. Thus there was continued urine and likely increased lung fluid contribution to the amniotic fluid. With fetal swallowing prevented, increased amniotic fluid volume would be expected. Notably, a 3day extrapolation of the control period volume swallowed (1196 ml) is similar to the measured increase in amniotic fluid volume (948 ml).

Although a control series of fetuses was not studied, Lingwood and Wintour²¹ noted amniotic fluid volume increases average <10 ml per day between 120 and

^{*}p < 0.05, versus day I control.

130 days' gestation and Tomoda et al.25 noted that amniotic fluid volume changed only "slightly from day to day." Furthermore, amniotic fluid volume did not appreciably increase in the single animal studied without esophageal occlusion. Thus the marked increased in amniotic fluid volume is likely a result of the esophageal occlusion and absent swallowing.

Hutchinson et al.,9 using isotope injections into the amniotic cavities of women, suggested that polyhydramnios was associated with differences in the rates of reciprocal transfer between mother, fetus, and amniotic fluid; however, these differences served to maintain an overall balance. Notably, this conclusion was derived from patients already diagnosed with polyhydramnios, whereas our study acutely induced polyhydramnios. Thus, in contrast to the present study, Hutchinson et al.9 did not observe the initial imbalance in fluid exchange resulting in polyhydramnios. The stable, though increased, amniotic volume, in the ovine fetus in which the esophagus was occluded at surgery, suggests that after the acute imbalance an equilibrium of transfer rates may occur. Although these findings concur, it is noteworthy that the diffusionary water flow measured by isotope techniques9 differs from the bulk water flow measured in the present study.

The only previous study¹³ examining ovine amniotic fluid in response to absent swallowing has several important differences from the present study. First, esophageal ligation was performed at the time of surgery rather than after postoperative recovery. Second, absent fetal swallowing was not confirmed. Third, fetal

Table III. Amniotic fluid values before (day 1) and after (day 4) esophageal occlusion

	Day 1	Day 4
Osmolality (mOsm/kg)	275 ± 3	278 ± 5
Sodium (mEq/L)	129.1 ± 2.6	130.1 ± 3.4
Potassium (mEq/L)	4.9 ± 0.6	6.4 ± 0.6
Chloride (mEq/L)	105.6 ± 3.3	110.8 ± 2.5

urine production was not determined, and, finally, the amniotic fluid volume was measured only at delivery weeks later. The present study demonstrates increased amniotic fluid volume after 3 days of esophageal occlusion, a time period not previously examined. The single fetus in which the esophagus was occluded at surgery demonstrated increased amniotic fluid volume on study day 1. Although potential compensatory changes in amniotic fluid production were not determined by Wintour et al.,13 the finding of normal amniotic fluid volume at delivery suggests that during chronic esophageal ligation alternative routes account for amniotic fluid resorption. The present study suggests a mincr contribution of fluid resorption from alternative routes as the increase in amniotic fluid volume (948 ml) was less than the sum of extrapolated urine volume and estimated lung fluid production rates.5 Together, these studies suggest that inhibition of ovine fetal swallowing may result in short-term, perhaps transient, polyhydramnios similar to that noted in the rhesus monkey. 12

In spite of the increase in amniotic fluid volume, there was no change in amniotic fluid composition. During the 4 days (80 hours) of study, fetal urine contributed (extrapolated) a net of 287 Osm and 1117 ml to the amniotic fluid, yielding an average urine osmolality of 257 mOsm/kg. This urine contribution, together with isotonic lung fluid, would likely maintain normal amniotic fluid osmolality (275 mOsm/kg) during the study period. Alternatively, amniotic fluid osmolality may be maintained by exchange of fluid and electrolytes to the mother⁹ or fetus⁸ across the amniotic membranes.

In the absence of swallowing, the fetus must acquire fluid by alternative routes to maintain urine and lung fluid production. The likely sources for this fluid influx include intramembranous or transplacental flow. As discussed above, intramembranous flow did not compensate for the increased amniotic fluid volume. Gresham et al. similarly concluded that the fetus is able to acquire large amounts of water during an 18-day period of continuous urine drainage (9250 ml). As they noted oligohydramnios at delivery, intramembranous flow or fetal swallowing could not have provided the fetus sufficient water. Thus we hypothesize that increased placental flow may provide the fetus sufficient body water to continue urine and lung fluid production in the absence of swallowing. The driving forces for increased placental flow are poorly understood, however.26 Nevertheless, the ability of the fetus to adapt to the presence or absence of significant volumes of ingested fluid illustrates the dynamic nature and potential magnitude of transplacental flow capabilities.

In summary, fetal esophageal occlusion evoked urinary hyperosmolality and markedly increased amniotic fluid volume within 3 days. These results indicate an important role of fetal swallowing in amniotic fluid volume homeostasis.

We thank Linda Day for technical assistance.

⁶⁶I think we've been stood up."

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg). Where protection begins

The physician should become familiar with the prescribing information (labeling) for this product, which discusses reported risks, such as thromboembolic disorders (including strokes and heart attacks), risk of estrogen dose, and hepatic lesions, as well as the need to monitor patients for early symptoms of any diseases or medical conditions, so use can be discontinued when appropriate.

Please see adjoining page for a brief summary of prescribing information.

The OC innovator **SEARLE**

BRIEF SUMMARY

Demulen® 1/35: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 35 mcg. Each blue tablet in Demulen 1/35: 28 is a placebo containing inert ingredients. Demulen® 1/50: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 50 mcg. Each pink tablet in Demulen 1/50: 28 is a placebo containing inert ingredients. Indication and usage: For prevention of pregnancy. Pregnancy rate for products with ≥35 mcg ethinyl estradiol or ≥50 mcg mestranol is ≤1/100 woman-years. With ≤35 mcg ethinyl estradiol, rate is slightly higher, with progestogen-only oral contraceptives (005), rate is about 3. Precise comparisons cannot be made. Rates for other methods have been published. Dose-related Thromboembolic Risk: Studies showed positive association between OC estrogen dose and thromboembolic its it is in keeping with good therapeutics to minimize estrogen exposure. Prescribe product containing least amount of estrogen compabile with acceptable prepanancy rate and patient acceptable year westers on ≤50 mcg estrogen. Cantralndications: Thromboembolic disorders, past history of deep vien thromboembolic bis classees, myocardial infarction or coronary attery disease, or past history of these: known or suspected breast carcinoma, estrogen-dependent neoplasia, or pregnancy: undiagnosed abnormal genital bleeding; past or present, benign or malignant liver tumors developing during use of estrogenic products.

Cigarette-smeking increases risk of serious cardiovascular side effects from OC use. Risk increases with age and heavy smoking (15 or more cigarettes/day) and is quite marked in women over 35. OC users should be strongly advised not to smoke. OCs are associated with increased risk of several serious conditions including venous and arterial thromboembolism, thrombotic and hemorrhage stroke, myocardial infraction, visual disorders, hepatic tumors, galibladder disease, hypertension, tetal abnormalities. Practitioners should be familiar with the available information relating to

these and other risks.

1. **Inromboembolic disorders** and other vascular problems: Increased risk of thromboembolic and thrombotic disease associated with OCs is well established. A British study showed increased risk for fatal venous thromboembolism (TE), British and U.S. studies showed increased risk for ratal venous thromboembolism (TE), British and U.S. studies showed increased risk for ratal venous thromboembolism (TE), British and U.S. studies showed increased risk for stoke. OC versil excess mortality from PE or stoke was 16.34, details/year/100,000 users and increased risk for thrombosis and pulmonary embolism (PE), projected hospitalization rates for ages 16-40 were 47/year/100,000 users and 5 for nonusers. Overall excess mortality from PE or stoke was 1.3-34, details/year/100,000 users and increased with age. *Cerebrovascular Disorders**. In a study of stroke with and without predispositions, risk of hemorrhagic stroke was 2 times greater and thrombotic stroke 4.0-9.5 times greater in users. Mortality trends in 21 countries incideate that changes in cardiovascular mortality were associated with changes in OC prevalence. The Royal College of GPG (RCGP) reported on its prospective study: "A statistically significant higher rate of reporting of cerebrovascular accidents in Takors is evident, but the numbers are too small to justily an estimation of the degree of risk." A 1981 analysis showed 4 4-fold increased mortality in users from circulatory diseases, mainly myocardial infarction (MI) and hemorrhagic stroke. Excess mortality was associated with age and smoking. A 1983 analysis showed elevated cerebrovascular disease, increasing with use to 8 yrs, including cerebral thromasis or embolism and TIA. Peripheral arterial diseases and MI were increased. Women over 30 had more arterial diseases, being greatest in sures who smoked. Family Planning Assoc, (PFA) found significant Mortality from nomenumatic heart disease was greater in ever-users. In the Walmut Creek Study, subarachnoid hemorrhage risk was ass

Estimated Mortality Rate from Myocardial Infarction per 100,000 Women/Year

Smokers and nonsmokers 5.4 1.9 32.8 11.7

Risk of Dose: Reports of TE after use of OCs with ≥50 mcg estrogen received by drug safety committees in Britain, Sweden, and Denmark were compared with distribution expected from marker research sales estimates. A positive correlation was found between estrogen dose and reporting of TE, including cornary thrombasis, in excess of that predicted by sales. OCs with ≥ 100 mcg estrogen were associated with higher TE risk than those with 50-80 mcg. Estrogen quantity may not be the sole factor: influence of progestogens was not considered, which may be responsible for certain discrepancies in the data. No significant differences were noted between OCs containing same estrogen dose no between enthinyl estraidol and mestranol. In Britain certain TE conditions were associated with progestogen or estrogen dose. In Sweden reports of TE decreased when higher estrogen doses were no longer prescribed. Studies on TE risk with progestogen-only OCs have not bendone. Cases have been reported for these; they are not presumed free of risk. In a U.S. case-controlled study, relative risk of OC use 1 month before hospitalization for various types of TE was calculated. If relative estrogenic potency and pose of different progestogens are ignored. OCs may be divided into those with <100 mcg and those with ≥ 100 mcg estrogen. For all cases combined, larger doses, but confidence limits overlapped and differences were not significant. Apparently there was less increased risk for cases with predispositions. In FPA study no nonhermorrhagic strokes occurred with <50 mcg estrogen, vs 13 with higher doses, but confidence from the control of the cont

Risk is: A-very high; B-high; C-moderate; D-low.	Age:	<30	30-39	≥40
Heavy smokers (≥ 15/day)		С	В	A
Light smokers (<15/day)		D	C	В
Nonsmokers, no predispositions		D	C,D	C
Nonsmokers, with predispositions		С	C,B	B,A

Nonsmokers, with predispositions

Be alert to earliest manifestations of TE disorders (eg. thrombophlebitis, PE, cerebovascular insufficiency, coronary artery disease, MI, retinal thrombosis, mesenteric thrombosis). Should any be suspected, discontinue OCs immediately, A 4-7-fold increased risk of postsurgery TE was reported in users; if feasible discontinue OCs at least 4 weeks before surgery or in protonged immobilization. Before resuming OCs, weigh risks of postsurgery TE complications against contraceptive needs. RCGP reported higher incidence of superficial and deep vein thrombosis in users, the former correlated with progestogen dose. Varicose veins have little effect on development of deep vein thrombosis. 2. Doutar lesions. Neuro-ocular lesions such as optic neurities or retinal thrombosis have been associated with OCs. Discontinue if there is unexplained, gradual or sudden, partial or complete loss of vision; proptosis or diplopia; papilledema; or evidence of retinal vascular lesions. Institute diagnostic and therapeutic measures. 3. Cerzionara: Long-term estropen in certain animals increases carcinomas and ronomalignant neoplasms, such as those of breast, uterus, cervix, vagina, ovary, liver, pituitary. Some synthetic progestogens, none currently in OCs, increase encidence of benign and malignant mammary nodules in dogs. Estrogens increase risk of human endomethial carcinoma. In case-controlled studies, increased endomethial carcinoma in Cese-controlled studies, increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcinoma in 600 supported by increased endomethial carcino

Atrial natriuretic factor responses to volume expansion in pregnant and nonpregnant sheep

Timothy L. Bennett, MD, and James C. Rose, PhDb

Kansas City, Kansas, and Winston-Salem, North Carolina

Isotonic volume expansion results in atrial natriuretic factor release by cardiac myocytes. Because pregnancy produces well-established alterations in fluid homeostasis and cardiovascular function, changes in atrial natriuretic factor responses may also occur. This study compares plasma atrial natriuretic factor responses to short-term volume expansion in pregnant and nonpregnant sheep. Seven pregnant and six nonpregnant ewes were chronically instrumented and subjected to a series of four experiments consisting of a control group (no infusion) and groups that received 10 ml/kg, 25 ml/kg, and 40 ml/kg isotonic saline infusion over a 30-minute period. The order of the experiments was random and separated by ≥48 hours. Plasma atrial natriuretic factor, osmolality, right atrial pressure, blood pressure, and urine flow were measured over a 150-minute observation period. After volume expansion, plasma atrial natriuretic factor levels rose significantly from 39 \pm 4 pg/ml (mean \pm SEM) to 49 \pm 7 pg/ml, 36 \pm 4 pg/ml to 62 \pm 19 pg/ml, and 39 ± 6 pg/ml to 67 ± 14 pg/ml in the nonpregnant group 10 ml/kg, 25 ml/kg, and 40 ml/kg experiments, respectively. In the pregnant groups, plasma atrial natriuretic factor levels rose from 50 ± 2 pg/ml to 75 \pm 20 pg/ml, 43 \pm 5 pg/ml to 57 \pm 5 pg/ml, and 46 \pm 4 pg/ml to 67 \pm 7 pg/ml, respectively. Differences in atrial natriuretic factor responses were not seen between pregnant and nonpregnant groups at any volume expansion level. As expected, atrial pressure and urine flow significantly increased after all volume expansion experiments. Pregnant and nonpregnant groups were similar with respect to atrial pressure and urine flow responses. Over various volume expansion levels significant associations were seen between atrial pressure, atrial natriuretic factor, and urine flow. These relationships were unaltered by pregnancy. In summary, atrial natriuretic factor responses to volume expansion do not appear to differ between pregnant and nonpregnant sheep. (AM J OBSTET GYNECOL 1991;165:1627-34.)

Key words: Plasma volume, urine flow, atrial pressure, vascular capacitance, cardiac compliance

Atrial natriuretic factor (ANF) is a polypeptide hormone released from cardiac atria in response to a variety of stimuli. Release is believed to be primarily a result of atrial stretch, although other mechanisms may be involved. 1.2 Isotonic volume expansion, for example, results in ANF secretion by increasing atrial pressure and volume. 3 ANF has potent effects on the cardio-vascular and renal systems, including reductions in cardiac output and blood pressure and increases in vascular compliance and urine flow. 4 Pregnancy also produces well-established changes in cardiovascular and renal function. 5 Cardiac output, blood volume, and glo-

merular filtration rate increase from 30% to 50% by late gestation in most mammals. Capacitance and compliance of the peripheral vasculature are also increased. Such physiologic responses are important to the development of the fetus.

Pregnancies failing to demonstrate blood volume expansion result in perinatal morbidity.6.7 Therefore given the gradual volume expansion present in normal pregnancy it is reasonable to question whether the regulation of ANF is altered. Information regarding the effect that pregnancy has on ANF release is limited. Although Cusson et al.8 reported increased plasma ANF levels with advancing gestation, most subsequent studies have shown little or no difference in pregnant and nonpregnant states. 9-11 Even less is known about the effect of pregnancy on ANF response to known stimuli. The ANF response to volume expansion has not been examined in pregnancy. Possible alterations in ANF release during pregnancy have potentially significant clinical relevance. Common diseases of pregnancy, including hypertensive disease, preeclampsia, cardiomyopathy, and tocolytic-associated pulmonary edema, may partially represent pathologically altered

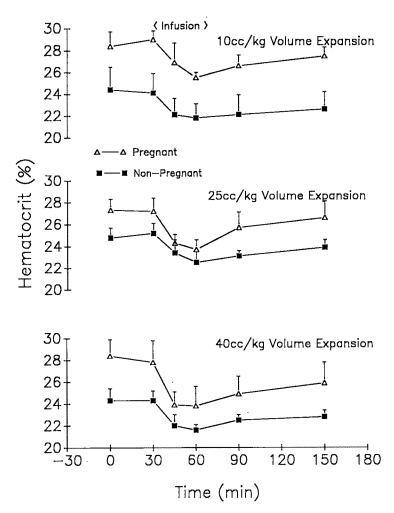

Fig. 1. Time course for hematocrit in 10 ml/kg, 25 ml/kg, and 40 ml/kg volume expansion experiments. Isotonic volume expansion began at 30 minutes and stopped at 60 minutes. After volume expansion, hematocrit fell at each volume expansion level (p = 0.05, 0.05, 0.01, respectively).

fluid homeostasis. Before any possible link between ANF and such conditions can be explored, the effects of normal pregnancy must be defined.

Our study is designed to compare plasma ANF levels in the pregnant and nonpregnant state and to examine the effect of pregnancy on ANF responses to volume expansion.

Material and methods

All procedures were performed with the approval of the Animal Care and Use Committee at Wake Forest University Medical Center. Seven pregnant ewes ranging from 110 to 139 days' gestation and six nonpregnant ewes were maintained in the facility several days before surgery. Each ewe was catheterized under general anesthesia. Polyvinyl catheters were placed in the fundus of the bladder for urine flow measurement and in the right atrium for pressure recording. Vascular catheters were inserted into a femoral vein for saline infusion and into a femoral artery for heart rate mon-

itoring blood pressure monitoring, and blood sampling. All catheters were exteriorized to the ewe's flank. Five days were allowed for surgical recovery.

Each ewe was subjected to a series of three volume expansion experiments and a control experiment. The order of these was randomly assigned and separated by at least 2 days. The experiments included a control (no infusion), 10 ml/kg, 25 ml/kg, and 40 ml/kg body weight isotonic saline infusion rapidly infused over 30 minutes. The time course consisted of an initial 30-minute observation period, a 30-minute infusion period, and a final 90-minute study period. All experiments were conducted with the ewes in standing position. Blood samples for ANF, hematocrit, and osmolality were drawn at 0, 30, 45, 60, 90, and 150 minutes. Urine volumes were measured at each of the above time segments and urine flow was calculated.

Plasma ANF was measured with radioimmunoassay techniques described elsewhere. ¹² Intraassay coefficient of variation was 8% and interassay 12%. Hematocrit

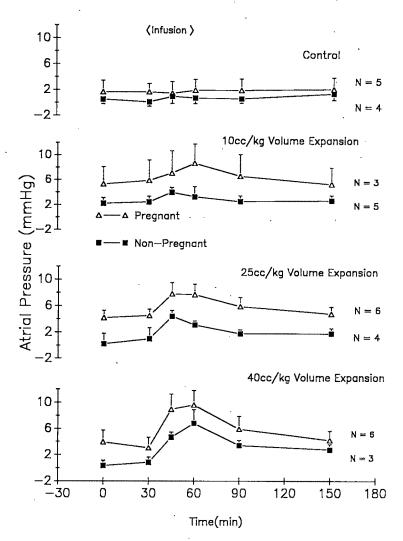

Fig. 2. Time course for right atrial pressure in control, 10 ml/kg, 25 ml/kg, and 40 ml/kg volume expansion experiments. Isotonic volume expansion began at 30 minutes and stopped at 60 minutes. Increases were noted after volume expansion (p = 0.02, 0.0001, 0.0001, respectively). No differences were noted between pregnant and nonpregnant groups at any volume expansion level.

was determined in duplicate with a microcapillary technique. Heart rate, arterial pressure, and atrial pressure were continuously monitored (recorder, Hewlett-Packard, Palo Alto, Calif.; IBM AT computer, IBM, Boca Raton, Fla.).

Because of the difficulty in maintaining catheters for extended periods of time, not all measurements were

available in each experiment. The number of measurements for each experiment is indicated in Figs. 1 through 5.

All data were expressed as mean ± SEM. Comparisons between nonpregnant and pregnant groups were made with a two-way analysis of variance with repeated measures for both volume expansion and time.13 Re1630 Bennett and Rose December 1991

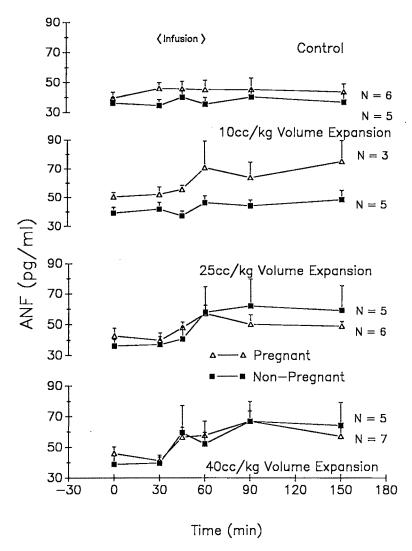

Fig. 3. Time course for plasma ANF in control, 10 ml/kg, 25 ml/kg, and 40 ml/kg volume expansion experiments. Isotonic volume expansion began at 30 minutes and stopped at 60 minutes. Increases were noted at each volume expansion level (p = 0.002, 0.002, and 0.003, respectively). No differences were noted between pregnant and nonpregnant groups at any volume expansion level.

lationships among atrial pressures, urine flows, and ANF responses were examined with regression analysis. Significance was set at $p \le 0.05$.

Results

Baseline values of all measured variables taken at the beginning of each control experiment are shown in Table I. Heart rate was higher in pregnant animals (p=0.01), but similar base values were seen for plasma ANF, right atrial pressure, hematocrit, mean arterial pressure, urine flow, and animal weight. After volume expansion, heart rate rose significantly in 25 ml/kg and 40 ml/kg volume expansion experiments. However, these changes were similar in pregnant and nonpregnant groups. An increase in mean arterial pressure was seen after volume expansion in 25 ml/kg and 40 ml/kg volume expansion experiments. Again, preg-

nant and nonpregnant groups failed to differ in mean arterial pressure response. As expected, hematocrit fell significantly in both pregnant and nonpregnant groups after volume expansion (Fig. 1). Although hematocrit values were slightly higher in the pregnant animals (p = 0.10), hematocrit changes were not different between groups for any volume expansion level.

Right atrial pressure rose significantly in all volume expansion experiments as compared with the control experiments (Fig. 2). Right atrial pressure had returned to baseline values by the conclusion of the experiment. At the beginning of all experiments right atrial pressure appeared higher in pregnant animals. This reached significance only in the 25 ml/kg volume expansion experiments. After volume expansion, however, changes in right atrial pressure were similar in pregnant and nonpregnant groups.

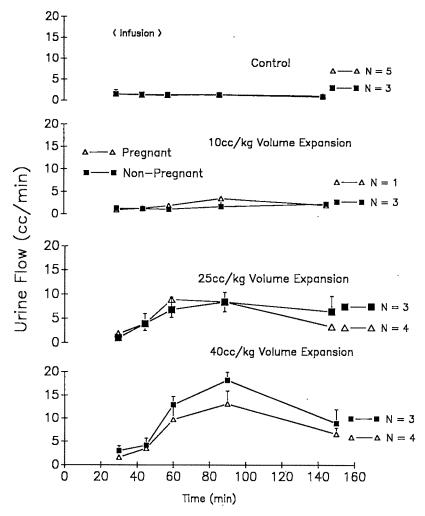

Fig. 4. Time course for urine flow in control, 10 ml/kg, 25 ml/kg, and 40 ml/kg volume expansion experiments. Isotonic volume expansion began at 30 minutes and stopped at 60 minutes. Increases in flow were seen at each volume expansion level (p = 0.002, 0.001, 0.001, respectively). Except for slightly increased response in nonpregnant group at 10 ml/kg volume expansion (p = 0.06), no differences were noted between pregnant and nonpregnant groups.

Baseline plasma ANF levels were not different between pregnant and nonpregnant groups (Fig. 3). After volume expansion, plasma ANF levels rose significantly from 39 ± 4 pg/ml (mean \pm SEM) to 49 ± 7 pg/ml, 36 ± 4 pg/ml to 62 ± 19 pg/ml, and 39 ± 6 pg/ml to 67 ± 14 pg/ml in the nonpregnant 10 ml/kg, 25 ml/kg, and 40 ml/kg experiments, respectively. In the pregnant groups, plasma ANF levels rose from 50 \pm 2 pg/ml to 75 \pm 20 pg/ml, 43 \pm 5 pg/ml to 57 \pm 5 pg/ml, and 46 \pm 4 pg/ml to 67 \pm 7 pg/ml, respectively. Although at 10 ml/kg volume expansion pregnant plasma ANF was slightly higher (p = 0.08) than the corresponding nonpregnant level, this trend was not seen at any other volume expansion level.

Prompt increases in urine flow were seen in all volume expansion experiments (Fig. 4). No significant differences were present between pregnant and nonpregnant groups for any volume expansion experiments.

Although all levels of volume expansion produced significant responses with regard to plasma ANF levels, atrial pressure, and urine flow, the 10 ml/kg and 25 ml/kg volume expansion experiments produced changes that were similar. At 40 ml/kg volume expansion, however, larger responses were seen in ANF (p = 0.05), atrial pressure (p = 0.01), and urine flow (p = 0.02).

When examining the effects of different variables on ANF response with multiple regression analysis, changes in right atrial pressure were most predictive of ANF response. Body weight, gestational age, heart rate, and pregnancy status all failed to appreciably relate to plasma ANF changes.

To analyze the relationship between plasma ANF, atrial pressure, and urine flow during volume expansion, maximal changes in these variables were compared. Fig. 5 shows the relationship between atrial pres-

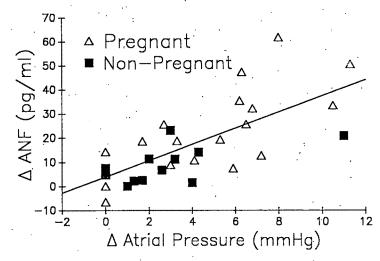

Fig. 5. Changes in right atrial pressure versus plasma ANF changes (r = 0.74, p = 0.0001). Values represent maximal changes in given variable during each experiment. All experiments are included for which measurements were available.

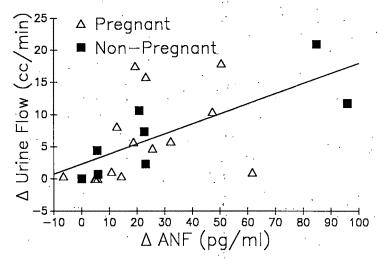

Fig. 6. Plasma ANF changes versus changes in urine flow (r = 0.62, p = 0.001). Values represent maximal changes in given variable during each experiment.

sure change and changes in ANF. The association appears to be linear and is similar in pregnant and nonpregnant experiments (r=0.74, p=0.0001). The regression line predicts an increase of 3.5 pg/ml in plasma ANF for every 1 mm Hg increase in right atrial pressure. The relationship between ANF response and urine flow changes is depicted in Fig. 6. Again, a linear association exists that is similar in pregnant and nonpregnant experiments (r=0.62, p=0.001). Besides ANF responses, right atrial pressure changes also predicted urine flow response as seen in Fig. 7 (r=0.72, p=0.001). This relationship was similar in pregnant and nonpregnant experiments.

Comment

In the current study pregnancy did not have a significant effect on basal plasma ANF levels or basal atrial pressures. Some investigators have postulated that ANF

levels should rise as a result of the large increase in plasma volume associated with pregnancy. This idea is consistent with the concept of pregnancy as an "overfill" state. Under such conditions ANF would rise as a result of increases in atrial pressure.18 However, our results agree with those of several studies mentioned previously that indicate little or no change in plasma ANF levels in pregnancy.9-11 These findings support pregnancy as an "underfill" state in which effective blood volume is not expanded. However, our understanding of the mechanism of ANF release and its metabolism is incomplete, and other explanations exist. Although atrial stretch is considered the chief stimulus for ANF release after volume expansion,3 the effects of pregnancy (specifically the hormonal changes accompanying pregnancy) on this mechanism remain unstudied. It can be speculated that homeostatic set-points undergo remodeling in the pregnant state. Also, ANF

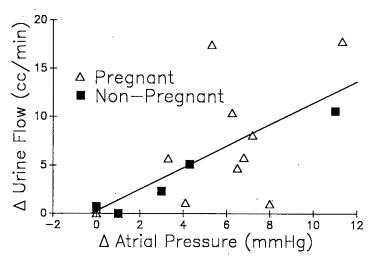

Fig. 7. Changes in right atrial pressure versus urine flow changes (r = 0.72, p = 0.001). Values represent maximal changes in given variable during each experiment.

release may increase during pregnancy but would not be reflected in increased plasma levels if clearance also increased. This is not without precedent, because the fetus demonstrates both increased release and clearance of this peptide as compared with the adult.14

Isotonic volume expansion produced significant elevations in plasma ANF at each volume expansion level in both the pregnant and nonpregnant groups. Thus these experiments confirm that pregnant animals exhibit an ANF response to volume expansion. In our experimental design volume expansion was normalized between pregnant and nonpregnant groups by adjusting the infused volume by body weight in keeping with the observations of Metcalfe and Parer¹⁵ that changes in blood volume are linearly correlated with body weight in sheep.15 Adjustment of each volume expansion level (10 ml/kg, 25 ml/kg, and 40 ml/kg body weight) resulted in very similar atrial pressure changes and dilutional changes in hematocrit in the pregnant and nonpregnant groups. Even though the pregnant animals received a larger absolute volume infusion, atrial pressures did not differ from nonpregnant animals and, most important, plasma ANF responses were not different. Because vascular capacitance is increased during pregnancy, effective blood volume may be reduced; it is possible that increased fluid loads might not be reflected by increased atrial pressure. Hatjis et al.12 reported no change in ANF levels in pregnant human subjects 20 minutes after acute volume expansion (25 ml/kg) in preparation for epidural anesthesia. The authors reasoned the lack of ANF response was caused by the enlarged (i.e., underfilled) vascular compartment.

Also, changes in cardiac compliance during pregnancy may alter the relationship between atrial pressure and atrial stretch. In these experiments, however, right atrial pressure changes were similar in pregnant and nonpregnant experiments, as were plasma ANF levels. In fact, the relationship between atrial pressure and ANF response was linearly correlated without respect to pregnancy status. This information suggests that in spite of all the changes in various hormones and volume status during pregnancy, the underlying mechanisms for ANF response to volume expansion remain intact and minimally altered.

After volume expansion, increases in urine flow may be partly attributable to plasma ANF increases, but many studies indicate such ANF effects on renal responses are minimal, compared with other hormonal and neural mechanisms. 16, 17 In this study a relationship was noted between ANF response and urine flow in both pregnant and nonpregnant groups. Although these experiments do not clarify whether this relationship is causal, they do suggest that the degree and type of relationship is unaltered by pregnancy.

Increases in volume expansion from 10 ml/kg to 25 ml/kg failed to significantly increase atrial pressure. It is not surprising that ANF also failed to show a larger response. When atrial pressure did increase significantly at 40 ml/kg volume expansion, ANF similarly changed. This finding supports atrial pressure as the primary stimulus for ANF release during volume expansion. Pregnancy demonstrated little impact on this interaction.

In summary, plasma ANF increased in adult sheep after isotonic volume expansion. Pregnancy appeared to have no effect on ANF response, nor did it affect relationships between atrial pressure and ANF response and between ANF response and urine flow.

We thank Drs. Frank Greiss, Jr., and Paul J. Meis for their support.

Fetal and maternal plasma atrial natriuretic factor responses to angiotensin II infusion

Michael G. Ross, MD,^a John P. Cardin, MD,^a Lony Castro, MD,^b M. Gore Ervin, PhD,^a and Rosemary D. Leake, MD^a

Torrance and Los Angeles, California

Plasma atrial natriuretic factor and angiotensin II have opposing actions in the regulation of body fluid homeostasis and systemic blood pressure. Angiotensin II infusions stimulate atrial natriuretic factor release in some, but not all, studies in adult mammals. To examine the response during the perinatal period, graded intravenous angiotensin II infusions were administered to four chronically instrumented pregnant ewes and fetuses (132 ± 1 days of gestation). Fetuses received successive 20-minute intravenous angiotensin II infusions at 25, 50, and 100 ng/kg/min. After a 90-minute recovery, maternal ewes received successive 20-minute angiotensin II infusions (5, 10, and 25 ng/kg/min). During the fetal infusions, mean (\pm SEM) fetal arterial blood pressure (47 \pm 2 to 61 \pm 2 mm Hg, ρ < 0.05) and heart rate (155 \pm 16 to 196 \pm 36 beats/min, p < 0.05) increased, although there was no change in maternal measured parameters. In response to the maternal infusion, maternal mean arterial blood pressure increased (92 \pm 7 to 110 \pm 8 mm Hg, p < 0.05) and maternal heart rate decreased (136 \pm 4 to 125 \pm 2 beats/min, p < 0.05) without change in fetal parameters. Fetal plasma atrial natriuretic factor levels $(210 \pm 27 \text{ to } 664 \pm 250 \text{ pg/ml}, p < 0.05)$ significantly increased during the fetal angiotensin II infusions in spite of no change in maternal plasma atrial natriuretic factor (85 ± 21 to 124 ± 22 pg/ml) during the maternal angiotensin II infusions. These findings indicate that similar increases in systemic blood pressure in response to angiotensin II infusions stimulate increased fetal, but not maternal, plasma atrial natriuretic factor. (AM J OBSTET GYNECOL 1991;165:1635-41.)

Key words: Angiotensin, atrial natriuretic factor, ovine fetus

The renin-angiotensin-aldosterone system and atrial natriuretic factor (ANF) interact in the regulation of body fluid homeostasis. Increased plasma ANF generally acts to decrease body water by urinary diuresis and natriuresis and to stimulate plasma-to-interstitial fluid flow.1.2 Conversely, aldosterone promotes renal sodium retention and extracellular volume expansion. During pregnancy these systems may contribute to maternal and fetal fluid homeostasis. Stimulation of the maternal renin-angiotensin-aldosterone system may be essential for appropriate maternal plasma volume expansion during pregnancy.3 In the puerperium increased maternal plasma ANF4 and suppression of renin³ may promote maternal diuresis and natriuresis, returning blood volume toward nonpregnant levels. Similarly, fetal renin-angiotensin and ANF may modulate in utero renal function and cardiac output distribution,⁵⁻⁸ whereas increased neonatal plasma ANF may contribute to the changes in newborn body water composition.⁹

The secretion of ANF and renin-angiotensin may also be interdependent. ANF has been demonstrated to inhibit renin secretion and angiotensin-mediated aldosterone release in vivo and in vitro. ¹⁰ Angiotensin II infusions stimulate ANF release in some, ¹¹ but not all, ¹² studies in adult mammals. However, the effect of angiotensin II infusion on plasma ANF has not been studied during pregnancy. In view of the potential importance of this interaction to fetal and maternal fluid homeostasis, we examined the ovine fetal and maternal plasma ANF responses to graded angiotensin II infusions.

Material and methods

Animals and surgery. Four Western cross-bred ewes and fetuses were studied. Guidelines for the care and use of animals approved by Harbor-University of California, Los Angeles Medical Center were followed, and the experimental procedures and protocol were approved by the Harbor-University of California, Los Angeles Animal Care Committee. Animals were maintained under controlled photoperiods of 12 hours light/12 hours dark and housed in individual steel study cages before and after operation. Both food (al-

falfa pellets) and water were freely available, except for the withholding of food during the 24-hour period before surgery. Anesthesia was induced by an intramuscular injection of ketamine hydrochloride (20 mg/kg) plus atropine sulfate (30 µg/kg) and subsequently maintained by a continuous intravenous infusion of ketamine (15 mg/kg/hr). Polyethylene catheters (inner diameter 1.0 mm, outer diameter 1.8 mm) were placed in the fetal dorsal hind limb artery and vein and threaded to the abdominal aorta and inferior vena cava, respectively. A plastic catheter (Corometrics Medical System, Wallingford, Conn.) was sutured to the distal tip of the fetal hind limb for measurement of intrauterine pressure, after which the uterus and the maternal abdominal wall were closed in layers. The maternal femoral artery and vein were catheterized and all catheters were exteriorized to the maternal flank and placed in a cloth pouch sewn to the ewe's flank. As described previously,13 all animals were provided a minimum of 5 days' postoperative recovery, during which time antibiotics were administered and catheters flushed.

Experimental protocol

Fetal infusion. All experiments were performed on unanesthetized ewes standing in the same individual cages in which they were maintained. The mean gestational age at the initiation of studies was 132 ± 1 day of gestation. On the day of study, fetal and maternal heart rate and blood pressure and amniotic fluid pressure were monitored during a 30-minute control period. Basal samples of maternal and fetal arterial blood (2.5 ml) were drawn at -30 minutes for measurement of hematocrit and plasma ANF level. An additional 0.5 ml sample of arterial blood was collected for immediate blood gas analysis. At time 0, intravenous infusions of angiotensin II in 0.15 mol/L saline solution (2 µg/ml) were administered to the fetus at 25, 50, and 100 ng/kg/min (maximum rate 0.05 ml/kg/min) for 20 minutes each. Before the infusions, the fetal catheters were filled with a volume of the angiotensin II solution equal to the catheter's dead space (1.0 ml). After the infusions, fetuses were monitored for an additional 30minute recovery period. Fetal body weight was estimated from the data of Robillard et al.14

FBW (kg) =
$$[0.096 \times \text{gestational age}]$$

(days)] - 9.2228

where FBW is fetal body weight. The angiotensin II infusate was prepared on the day of infusion by dissolving the preweighed 5-valine angiotensin II (Bachem, Torrance, Calif.) in normal saline solution. Fetal blood samples for hematocrit, plasma ANF, pH, and blood gases were obtained at 20, 40, 60, and 90 minutes after initiation of the infusion. Maternal blood samples were repeated at the conclusion of the final infusion (60 minutes).

Maternal infusion. After the fetal recovery period and an additional 1-hour period, intravenous infusions of angiotensin II (5, 10, and 25 ng/kg/min) were administered to the maternal ewes by an identical protocol. The reduced maternal angiotensin II doses were selected to achieve equivalent dose-dependent increases in fetal and adult plasma angiotensin II concentrations. Throughout both studies, all fetal blood samples were immediately replaced with equivalent volumes of heparinized maternal blood drawn before the study, and all maternal samples were immediately replaced with equivalent volumes of saline solution.

Analytic methods. Maternal and fetal heart rate and blood pressures and amniotic fluid pressures were monitored with a Beckman R-612 physiologic recorder (Beckman, Palo Alto, Calif.) and Statham P-23 DB pressure transducers (Gould, Inc., Cleveland). Fetal blood pressure was corrected for amniotic fluid pressure. Blood samples were transferred immediately to chilled test tubes containing aprotinin (250 kallikrein units per milliliter of blood), trypsin inhibitor (40 µU/ml), and 15% ethylenediaminetetraacetic acid (10 µl/ml) for determination of plasma ANF. All tubes were mixed and centrifuged immediately at 4° C, and the plasma was separated and frozen for later assay. Hematocrit determinations were performed in duplicate on each blood sample. Blood pH, Po2, and Pco2 values were measured at 39° C with a model BM 33 MK2-PHM 72 MKS acid-base analyzer system (Radiometer Co., Copenhagen).

Plasma ANF concentrations were measured by radioimmunoassay as previously described.¹⁵ The ANF radioimmunoassay is sensitive to 10 pg/ml, with intraassay and interassay coefficients of variation of 5% and 11%, respectively.

Calculations and statistics. All values are expressed as the mean \pm SEM. Plasma ANF levels were log transformed after determination of nonnormality by the Wilk-Shapiro test. Differences over time were assessed by analysis of variance with trends in the data considered statistically significant when the F test yielded a p < 0.05. Differences between time periods were determined with Dunnett's test at a p < 0.05 level of significance. For the analysis of angiotensin II dose-response effects, linear regression was performed for maternal and fetal blood pressures (systolic, diastolic, and mean) versus angiotensin II infusion doses.

Results

Fetal infusions. In response to the intravenous angiotensin II infusions, fetal systolic, diastolic, and mean blood pressures significantly increased (Fig. 1, Table I) and returned to basal values during the recovery period. Regression analysis revealed significant correlations of fetal mean systolic and diastolic blood pressures with angiotensin II infusion doses; r values ranged from

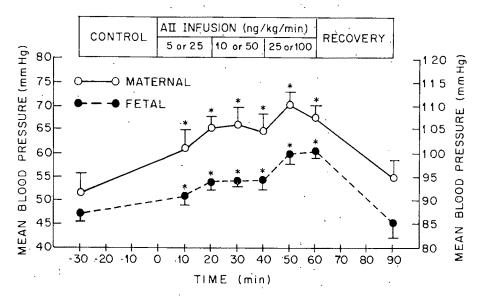

Fig. 1. Maternal (solid line, right vertical axis) and fetal (dashed line, left vertical axis) mean arterial pressure before, during, and after graded intravenous angiotensin II infusions.

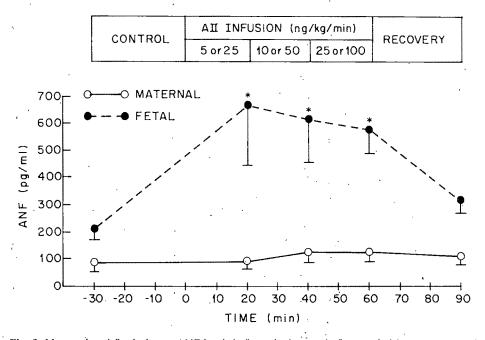

Fig. 2. Maternal and fetal plasma ANF levels before, during, and after graded intravenous angiotensin II infusions.

0.69 to 0.80 (Table II). Basal fetal plasma ANF (210 ± 27 pg/ml) significantly increased more than threefold in response to the 25 ng/kg/min angiotensin II infusion (Fig. 2). In spite of continued increases in fetal blood pressure, no further change in fetal plasma ANF occurred. Plasma ANF returned toward basal values at the conclusion of the recovery period. Fetal heart rate increased significantly in response to the 50 and 100 ng/kg/min infusion rates (Table I). Fetal hematocrit, pH, PO2, and PCO2 did not change during the study.

There was no change from basal levels of maternal hematocrit (30.5% \pm 2.6%), pH (7.46 \pm 0.05), PO₂

 $(99 \pm 3 \text{ mm Hg})$, Pco_2 $(35 \pm 4 \text{ mm Hg})$, mean blood pressure (96 \pm 12 mm Hg), or heart rate (148 \pm 4 beats/min) during the fetal angiotensin II infusion.

Maternal infusions. In response to the angiotensin II infusions to the ewe, maternal systolic, diastolic, and mean blood pressures significantly increased (Fig. 1, Table III). Increases in maternal mean and diastolic, but not systolic, blood pressures were significantly correlated with the angiotensin II infusion doses. However, r values for mean and diastolic blood pressures were only 0.44 and 0.50, respectively (Table II). Maternal heart rate decreased significantly in response to 1638 Ross et al.

Comment

Infusion of angiotensin II to the ovine fetus and ewe resulted in similar (10 to 20 mm Hg) increases in maternal and fetal mean blood pressures. The higher fetal angiotensin II infusion rates we used were due to the increased plasma clearance rate in late gestation ovine fetuses, as compared with adult ewes. Using similar fetal (26, 48, 97 ng/kg/min) and adult (5, 10, 20 ng/kg/min) angiotensin II infusion rates, Robillard et al. Achieved nearly equivalent dose-dependent increases in fetal and adult plasma angiotensin II concentrations from approximately 50 to 350 pg/ml; peak levels were similar to those measured in response to hemorrhage or hypotension. The 20-minute infusion

period was based on previous studies demonstrating steady-state plasma angiotensin II levels and stable measurements of mean arterial blood pressure at 10, 15, and 20 minutes of intravenous infusion.¹⁵

Fetal mean, systolic, and diastolic arterial blood pressures displayed significant dose-dependent increases in response to angiotensin II infusions (Table II). Notably, absolute increases in fetal arterial blood pressure were less than those demonstrated in recent fetal angiotensin II infusion dose-response studies. ^{16, 17} However, Clark et al. ¹⁶ used dosages of 100 to 3000 ng/kg/min, whereas Yoshimura et al. ¹⁷ used dosages ranging from 3 log units, with fetal dosages approaching 1500 ng/kg/min. Our results are consistent with these studies in demonstrating a statistically significant, although smaller, blood pressure dose response within a physiologic range of fetal angiotensin II infusions (25 to 100 ng/kg/min).

As a result of the nearly equivalent absolute increases in fetal and maternal blood pressures, there was a smaller relative increase in maternal blood pressure. Although angiotensin II infusions did induce dose-dependent increases in maternal mean and diastolic blood pressures, the correlations were not as great as with fetal blood pressures. Perales et al.¹⁸ previously demonstrated dose-related increases in mean arterial pres-

sure in pregnant ewes, although the dosages administered (1.15, 2.29, and 11.5 µg/min) were up to tenfold greater than the dosages in our study or that of Robillard et al.8 Notably the lowest dose used by Perales et al. (1.15 µg/min) achieved a similar increase in maternal mean arterial blood pressure as the maximum dose in our study. Bruce et al.19 similarly demonstrated dosedependent increases in ovine maternal blood pressure using a dosage range of 2 to 200 ng/kg/min. However, a review of their results¹⁷ indicates minimal increases in maternal blood pressure within the dosage range of 2 to 25 ng/kg/min. Importantly, Naden et al. 15 reported a markedly reduced angiotensin II pressor response during ovine pregnancy. Although it is possible that a tachyphylaxis to the successive infusions accounted for the reduced maternal blood pressure response, downregulation of angiotensin II receptor number likely would require longer than 20-minute infusion periods.20

Consistent with previous reports, 7.8, 18 the current experiments were notable for significant increases in fetal heart rate, with a small, although significant, decrease in maternal heart rate. Although the mechanism of the positive fetal chronotropic response is not clear, it may result from direct cardiac effects of angiotensin II or alterations in sympathetic and parasympathetic tone.7 The negative maternal chronotropic response is likely baroreceptor mediated. Neither the current study nor previous reports8, 18 detected a change in fetal or maternal blood gases, pH, or hematocrit during the angiotensin II infusions.

The angiotensin II infusions resulted in a significant increase in fetal, but not maternal, plasma ANF. ANF is present and may be released from both left and right adult atria21 in response to atrial stretch or increased atrial pressure.22 In response to angiotensin II-induced arterial constriction, increased cardiac afterload, left ventricular end-diastolic pressure, and perhaps left atrial pressure may be responsible for ANF release in dogs23 and rats.11 Conversely, norepinephrine, but not angiotensin II, increased left atrial echocardiographic area and plasma ANF in human volunteers, in spite of similar elevations in mean arterial pressure.¹² In the absence of atrial and venous pressure measurements in our study, the regulation of ovine ANF release by atrial pressure cannot be determined. Nevertheless, the results of this study suggest that the behavior of the adult sheep is similar to that of the human in failing to exhibit an ANF response to angiotensin II. Alternatively, the maternal ANF response may be a secondary effect of the reduced maternal angiotensin II pressor effect; the blood pressure threshold for maternal ANF release may be greater than that achieved in the present study.

Fetal plasma ANF levels increased threefold at the lowest angiotensin II infusion rate and remained elevated throughout the higher-dose infusions. The increase in fetal, but not maternal, ANF levels suggests differences in either the distribution and content of cardiac ANF or the cardiovascular response to angiotensin II. The ontogeny of ANF in the developing heart has been examined in both human and rat fetuses. In fetal and neonatal rat atria, relative ANF content (concentration per milligram of protein) increases with time.24 Fetal rat ventricular ANF content is high, although it rapidly decreases to minimal values in the adult.24, 25 In the developing human heart, right and left ventricular ANF contents similarly decrease with advancing gestation. 19, 26 Right atrial ANF content has been demonstrated as both greater19 and less26 than left atrial content during fetal life. In response to the fetal angiotensin II infusion, increased cardiac afterload and systemic blood pressure likely resulted in increased ventricular end-diastolic pressure. Although afterloadinduced ventricular ANF release has not been demonstrated, it is possible that fetal ventricular ANF contributed to the increased plasma ANF concentration in response to the angiotensin II infusion. In addition, reduced ANF clearance, in association with angiotensin II—mediated decreases in renal and placental blood flow,⁷ may also have contributed to the increase in plasma ANF.

The fetal angiotensin II infusion was administered before the maternal infusion in all cases to avoid a potential efect of maternal angiotensin II on fetal oxygenation and heart rate. However, decreased uterine blood flow and fetal effects of maternal angiotensin II infusions have been demonstrated only in response to pharmacologic dosages (110 to 200 ng/kg/min¹⁷ or 11.5 µg/min¹⁶). There was no evidence of altered fetal oxygenation in response to fetal or maternal angiotensin II infusions; therefore hypoxia does not appear to have contributed to fetal ANF release.²⁷

The stimulation of plasma ANF by angiotensin II infusion in the fetus but not the pregnant ewe has several important implications. First, relatively minor degrees of fetal hemorrhage result in a marked increase in plasma angiotensin II levels,28 which contribute importantly to fetal cardiovascular homeostasis.29 Increased fetal plasma angiotensin II results in significant changes in fetal cardiac output and blood flow distribution. As ANF has significant fetal cardiovascular effects, the angiotensin II-induced alterations may be mediated in part by ANF release. Second, the lack of a maternal ANF response to angiotensin II infusion may be a reflection of the reduced pressor sensitivity during pregnancy. 15 Mechanisms postulated for the reduced pressor responsiveness of pregnancy have included effects of increased prostacyclin, estrogen, and progesterone and down-regulation of angiotensin II receptors.30 Whether a greater increase in maternal blood pressure would have stimulated ANF is uncertain. However, because ANF may stimulate natriuresis, diuresis, and loss of intravascular volume, a maternal resistance to angiotensin II-stimulated ANF release would be of protective value in the hemorrhage-prone state of pregnancy.

In conclusion, the current study demonstrates significant increases in fetal, but not maternal, plasma ANF levels in response to similar, absolute increases in systemic blood pressure during angiotensin II infusion.

Angiotensin II vascular smooth-muscle receptors are not down-regulated in near-term pregnant sheep

Hasu R. Mackanjee, MB, ChB, Philip W. Shaul, MD, Ronald R. Magness, PhD, and Charles R. Rosenfeld, MD

Dallas, Texas

Normal human and ovine pregnancies are associated with elevated plasma angiotensin II levels and refractoriness to the vasoconstrictor effects of infused angiotensin II, which is greater in the ovine uteroplacental vascular bed than in the systemic vasculature. It remains unclear whether this refractoriness reflects alterations in angiotensin II vascular smooth-muscle receptor density or affinity. We examined the angiotensin II vascular smooth-muscle receptor in nonpregnant (n=12) and near-term pregnant (130 ± 3 days [mean \pm SD], n=10) sheep, comparing binding characteristics on plasma membranes prepared from the medial layer of aorta, mesenteric artery, and uterine artery. Plasma angiotensin II levels were increased threefold to fourfold (p<0.001) in pregnant ewes. A single class of high-affinity angiotensin II vascular smooth-muscle receptor was identified in each type of artery. Receptor density was similar in nonpregnant and pregnant mesenteric artery (92 ± 21 vs 103 ± 40 fmol/mg protein, respectively), aorta (186 ± 29 vs 220 ± 46 fmol/mg protein), and uterine artery (59 ± 20 vs 77 ± 20 fmol/mg protein) tissue. Receptor affinity also was unchanged during pregnancy. Because changes in the density and affinity of the angiotensin II vascular smooth-muscle receptor were not observed in near-term pregnant ewes, the attenuated vasoconstrictor responses seen during pregnancy do not reflect receptor down-regulation or decreased affinity. (AM J OBSTET GYNECOL 1991;165:1641-8.)

Normal pregnancy is characterized by numerous cardiovascular and hormonal alterations such as increases in cardiac output, decreases in systemic vascular resistance, development of the low-resistance uteroplacental vascular bed, and activation of the renin-angiotensin system, which is reflected by increased circulating levels of plasma renin activity and angiotensin II. Of particular interest has been the observation that normal pregnancy is also associated with the development of relative

refractoriness to the systemic pressor effects of infused angiotensin II.² This aspect of cardiovascular adaptation has been of substantial importance because this refractoriness to angiotensin II is lost early in the midtrimester in women destined to develop pregnancy-induced hypertension well before they demonstrate an elevation in blood pressure.² The mechanism(s) responsible for this refractoriness to infused angiotensin II during normal pregnancy and for its absence in women who have pregnancy-induced hypertension remains unclear.

Although pregnant sheep do not develop pregnancyinduced hypertension, they have been observed to develop many of the cardiovascular and hormonal changes reported in normal human pregnancy.3 The pregnant ewe,4.5 like women2 and several other species,6,7 develops refractoriness to infused angiotensin II in the face of increased plasma levels of this peptide and plasma renin activity.8, 9 Moreover, the dose-response curves and the effective pressor dose of angiotensin II, that is, the dose necessary to elicit a 20 mm Hg rise in blood pressure in the ewe, are strikingly similar to those reported in women.2,4 This model, however, is unique in that uteroplacental blood flow can be continuously monitored, and we have shown that this vascular bed is even more refractory to the vasoconstrictor effects of angiotensin II than the systemic vascular bed.10, 11 Using this model to study adaptive mechanisms in normal pregnancy, we have demonstrated that the attenuated systemic pressor response to angiotensin II does not reflect increases in the baroreceptor reflex12 or increased clearance of the peptide.9 We⁸ also have confirmed observations in normal pregnant women¹⁵ that acute decreases in plasma renin activity do not alter pressor responses to infused angiotensin II; these observations suggest that down-regulation of the angiotensin II vascular smooth-muscle receptor may not explain this phenomenon. This conclusion, however, is in conflict with that of Siddiqi et al.,14 who demonstrated an increase in vascular responsiveness to infused angiotensin II in pregnant ewes after 24 hours' treatment with enalapril, an angiotensinconverting enzyme inhibitor. In the few reports in which the angiotensin II receptor has been studied, alterations in nonvascular smooth-muscle angiotensin II receptors, but not the vascular smooth-muscle receptor, has been examined.7, 15, 16 Thus we sought to determine whether the attenuated responses to angiotensin II observed in the uteroplacental and systemic vascular beds of the pregnant ewe reflect down-regulation of the angiotensin II vascular smooth-muscle receptor and, if so, whether this is different in the uterine and systemic vascular beds.

Material and methods

Pregnant (n = 10) and nonpregnant (n = 12) ewes

versity of Texas Bastrop breeding facility and maintained on standard animal chow (Purina Commercial Creep II, G, Purina Mills, St. Louis) and given free access to water until killed (130 \pm 3 days, term 144 \pm 3 days, mean \pm SD). Animals were placed into two study groups: In the first group we examined the systemic vascular smooth-muscle receptor in the mesenteric artery and aorta of pregnant (n = 5) and nonpregnant (n = 6) ewes. In the second group we examined the uterine and mesenteric arteries in similar numbers of pregnant and nonpregnant animals. This separation into two groups was necessitated by the need to simultaneously study two arteries in each animal. After jugular venous blood was obtained for measurement of plasma angiotensin II animals were killed by the rapid intravenous injection of pentobarbital sodium (50 mg/kg). Immediately thereafter the mesenteric arteries extending from the first- to the third-generation arcades and the entire abdominal aorta were removed. For studies of the uterine arteries, vessels extending from the first to the fourth generations were obtained. Arteries used in these studies were dissected and removed from all animals by the same investigators (H.R.M. and R.R.M.) to ensure that the areas sampled were the same. Arteries were removed with minimal trauma, immediately placed in ice-cold 8 mmol/L phosphate-buffered saline solution (pH 7.4), and rinsed free of residual blood. Fat, connective tissue, and adventitia were dissected from the arteries and the endothelium removed with a cotton-tipped applicator. The remaining medial layer provided the source of smooth muscle examined. These studies were approved by the Institutional Review Board for Animal Research.

Receptor radioligand binding studies. After removal of the endothelium, the medial smooth muscle (1.0 to 1.5 gm wet weight) was transferred into 20 ml of ice-cold 0.25 mol/L sucrose with 10 mmol/L Tris buffer, pH 7.4, and minced. Plasma membranes were prepared at 4° C by modifications of the methods of Baker et al.17 With a probe (Polytron PT-20, Brinkman Instruments, Westbury, N.Y.), tissue was homogenized three times for 8 seconds; the probe was allowed to cool between homogenizations. The protease inhibitors phenylmethylsulfonyl fluoride (0.5 mmol/L), leupeptin (5 μ g/ml), and aprotinin (5 μ g/ml) were added to the homogenate. The homogenate was centrifuged at 4° C at 10,000g for 20 minutes, and the supernatant was decanted, filtered through two layers of gauze, and centrifuged at 4° C at 45,000g for 30 minutes. The resulting pellet was resuspended in 5 ml of 0.6 mol/L potassium chloride, 30 mmol/L histidine buffer (pH 7.0) to solubilize actin and myosin and recentrifuged at 4° C at 45,000g for 30 minutes. The final pellet was resuspended in 25 mmol/L Tris buffer (pH 7.5) with 10 mmol/L magnesium chloride, 10 μg/ml bacitracin, 0.5 mmol/L dithiothreitol, and 0.2% bovine serum al-

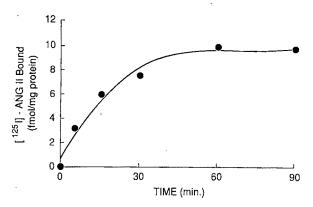

Fig. 1. Representative time to equilibrium study for incubation of vascular smooth-muscle receptor plasma membranes with 125 I-angiotensin II (ANG II). Plasma membranes were prepared from nonpregnant aorta and studied at 18° C. Specifically bound 125 I - angiotensin II is plotted as a function of incubation time; each point was determined in duplicate.

ranged from 80 µg/100 µl to 130 µg/100 µl as determined by modification of the Lowry method.18

Angiotensin II receptor binding assays were performed with 100 µl of membrane preparation in a total volume of 150 µl of the 25 mmol/L Tris buffer with 0.2% bovine serum albumin. Freshly prepared membranes were used in all experiments because binding was found to decrease with storage. Tyrosyl iodine 125labeled [5-L-isoleucine] angiotensin II (125 I - angiotensin II, New England Nuclear Corp., Boston, Mass.) was added in concentrations from 0.3 to 0.4 nmol/L. Unlabeled angiotensin II was added in increasing amounts from 10⁻¹¹ mol/L to 10⁻⁸ mol/L; the binding characteristics were determined from analysis of the displacement of labeled ligand with the methods of Baker et al.17 Nonspecific binding was determined by the addition of 10⁻⁵ mol/L angiotensin II. Specific binding of ¹²⁵I-angiotensin II reached equilibrium by 60 minutes of incubation for each artery studied (Fig. 1); therefore 60-minute incubations were used in all binding studies. Linearity of specific radioligand binding versus the amount of membrane protein incubated was confirmed (Fig. 2). Competitive binding studies were performed with 10^{-10} mol/L to 10^{-5} mol/L unlabeled angiotensin II, angiotensin III, angiotensin I, Sar¹, Thr⁸-angiotensin II, and arginine vasopressin (Sigma Chemical Co., St. Louis). Incubations for binding assays were performed at 18° C and were terminated by rapid addition of 4 ml of ice-cold 25 mmol/L Tris buffer with 0.2% bovine serum albumin. Bound and free ligands were then immediately separated by filtration through filters (Whatman GF/C, Whatman International Ltd., Maidstone, England) under vacuum, after which the filters were rinsed three times with buffer. After drying, radioactivity collected on the filter was determined with a scintillation counter (Packard Instruments, Downers Grove, Ill.) with an efficiency of 70% for 125 I. Binding

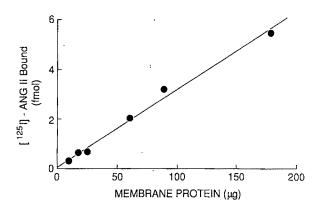

Fig. 2. Representative study of linearity of specific 125 I - angiotensin II (ANG II) binding versus amount of plasma membrane protein incubated for 60 minutes at 18° C. Plasma membranes were prepared from nonpregnant aorta. Each point was determined in duplicate.

paired arteries obtained from the same animal; all determinations were performed in duplicate.

The density of angiotensin II vascular smooth-muscle receptor (B_{max}) and the dissociation constant (K_d) were calculated from the specific binding data with a modification of the computer program LIGAND¹⁹ adapted for microcomputers by McPherson (Elsevier BIOSOFT, Cambridge, England).20 Hill coefficients were calculated from the same program.21

Plasma angiotensin II assay. Jugular venous blood (6 ml) was collected in chilled plastic syringes, immediately placed in cold tubes containing ethylenediaminetetraacetic acid and 60 µl of 0.125 mol/L 1,10phenanthroline, and centrifuged at 4° C; plasma was separated and stored at -20° C until the time of assay. The methods for extraction and the radioimmunoassay procedures have been previously published.9 The sensitivity of the assay was 1.3 pg per tube, and the recovery was $73\% \pm 2$ (mean \pm SEM). Cross-reactivity of the antiserum (titer 1:15,000) was 0.72% for angiotensin I, 22.6% for [Des-Asp¹]-angiotensin I, and 77.2% for [Des-Asp¹]-angiotensin II. Within-assay variability was determined from replicants (n = 6) of three plasma pools obtained from sheep and was 7.1%, 5.9%, and 5.6%. Between-assay variation was determined by assigning samples from these pools (n = 6) in each assay and was 10.4%, 9.2%, and 8.7%.

Statistical methods. Binding characteristics for different arteries and groups were compared with analysis of variance and Newman-Keuls test for multiple comparisons. Matched data were compared by using Student's t test. All data are presented as mean \pm SD unless otherwise noted.

Results

Plasma angiotensin II. Venous plasma concentrations of angiotensin II in the first group of ewes were

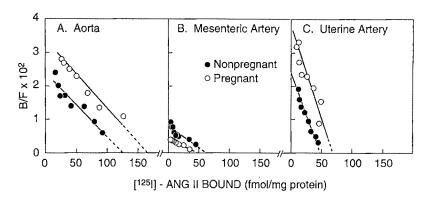

Fig. 3. Representative Scatchard plots of 125 I—angiotensin II (ANG II) binding to plasma membrane fractions prepared from aorta (A), mesenteric arteries (B), and uterine arteries (C) obtained from nonpregnant (solid circle) and pregnant (open circle) ewes. Ratio of bound to free $(B/F)^{125}$ I—angiotensin II is plotted as a function of specifically bound 125 I—angiotensin II. Each point was determined in duplicate.

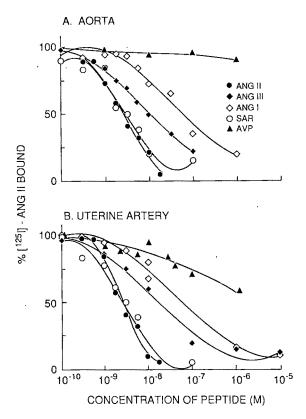

Fig. 4. Displacement curves for ¹²⁵I-angiotensin II (ANG II) binding to plasma membrane fractions from aorta (A) and uterine artery (B). Values are means of three to six experiments with each peptide, each performed in duplicate. SAR, [Sar³, Thr³]-angiotensin II; AVP, arginine vasopressin.

with nonpregnant (n = 6), 30 ± 7.6 pg/ml (0.03 nmol/L) and 6.7 ± 1.3 pg/ml (0.007 nmol/L) (p < 0.001), respectively. Similar results were obtained in the second group of ewes, that is, 29 ± 6.7 pg/ml (0.03 nmol/L) and 8.4 ± 1.7 pg/ml (0.008 nmol/L)

(p < 0.001), respectively, a 3.5-fold rise during pregnancy.

Angiotensin II receptors. LIGAND analysis of the displacement of 125 I—angiotensin II by unlabeled angiotensin II demonstrated a one-site model (p < 0.05, r > 0.90) and thus a single class of saturable binding sites. Representative Scatchard plots of specific binding data are presented in Fig. 3 for each of the arteries studied from nonpregnant and pregnant sheep. Specific binding at K_a was generally >80%; the vast majority of nonspecific binding was accounted for by binding of the radioligand to the filters. This was not altered by prewetting the filters with albumin-containing buffer. Hill coefficients ranged from 0.97 to 1.02, indicating that cooperativity was not involved in the binding of 125 I—angiotensin II to the vascular smooth-muscle receptor. 21

The ability of several angiotensin II analogues and the unrelated peptide hormone arginine vasopressin to displace ¹²⁵I—angiotensin II was examined. Representative displacement curves for vascular smooth muscle from aorta and uterine artery are illustrated in Fig. 4. The order of potency was saralasin = angiotensin II > angiotensin III > angiotensin I (inhibitory concentration of 50%: 5, 4, 18, and 80 nmol/L). Vasopressin did not displace ¹²³I—angiotensin II except at high concentrations. These findings are characteristic of binding to angiotensin II receptors.²²

In the first group of animals we examined the binding characteristics in two systemic arteries, the aorta and mesenteric arteries. Although $B_{\rm max}$ was more than twofold greater (p < 0.05) in the aorta as compared with the mesenteric artery in both nonpregnant (186 ± 29 fmol/mg protein vs 92 ± 21 fmol/mg protein) and pregnant (220 ± 46 fmol/mg protein) are greater was no difference between nonpregnant and pregnant receptor density for either vessel. The K_d for both systemic

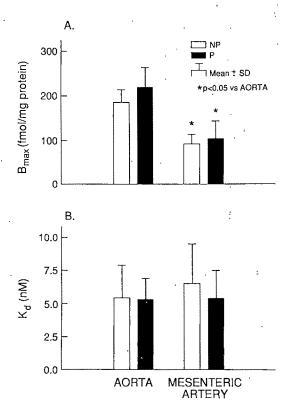

Fig. 5. Effect of pregnancy on angiotensin II receptor—binding density (B_{max}) (A) and dissociation constants (K_d) (B) in ovine aorta (n = 5) and mesenteric artery (n = 5). P, Pregnant; NP, nonpregnant.

In the second group of animals we compared the angiotensin II vascular smooth-muscle receptor in the systemic, that is, the mesenteric artery, and uterine arteries (Fig. 6). As in the first group there was no difference in B_{max} or K_d in the mesenteric artery of nonpregnant versus pregnant (78 ± 14 fmol/mg protein vs 61 ± 21 fmol/mg protein) ewes. Furthermore, these values were similar to those seen in the first group. Receptor density in the uterine artery also was not different in nonpregnant versus pregnant (59 \pm 20 fmol/mg protein vs 77 ± 20 fmol/mg protein), as was the K_d. Although the values for receptor density were similar to those seen in the mesenteric artery, the K_d in the mesenteric artery was 88% to 96% greater than that for nonpregnant or pregnant uterine artery vascular smooth-muscle receptor.

Comment

Regulation of the angiotensin II vascular smoothmuscle receptor during pregnancy remains an enigma; whether it is down-regulated and this accounts for the attenuated pressor responses to infused angiotensin II

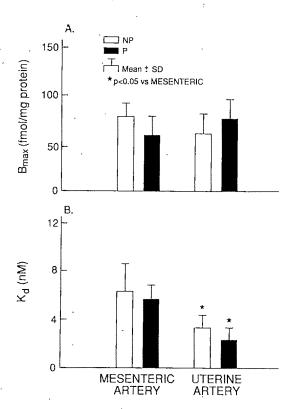

Fig. 6. Effect of pregnancy on angiotensin II receptor binding density (B_{nuc}) (A) and dissociation constants (K_d) (B) in ovine mesenteric (n = 5) and uterine (n = 5) artery. P, Pregnant; NP, nonpregnant.

seen in pregnant women² and several other species⁴⁻⁷ is controversial. This controversy emanates from studies in women and animals from which it has been suggested that down-regulation of the angiotensin II vascular smooth-muscle receptor either does14,16 or does not8,13 occur during normal pregnancy. In our investigation we identified a single class of high-affinity angiotensin II receptors in vascular smooth muscle of three different arteries obtained from normal pregnant and nonpregnant ewes with binding characteristics similar to those reported by others.²² More specifically we provide evidence for the first time that the B_{max} in systemic arteries does not decrease in spite of a threefold to fourfold increase in circulating levels of angiotensin II during ovine pregnancy, and the affinity is also unchanged. Thus it is unlikely that the attenuated pressor responses observed during ovine pregnancy,4.5 which are strikingly similar to that seen in human pregnancy,2 can be explained by these mechanisms. Furthermore our observation of an even greater refractoriness to the vasoconstrictor effects of angiotensin II in the uteroplacental vascular bed as compared with the systemic vasculature10,11 also cannot be explained by a decrease in the density or affinity of the uterine artery angiotensin II vascular smooth-muscle receptor. It is note1646 Mackanjee et al.

December 1991

Am J Obstet Gynecol

worthy that the K_d for each of these vessels was similar to the plasma concentration of angiotensin II necessary to elicit a 50% rise in mean arterial pressure in pregnant and nonpregnant ewes^{4, 9} (i.e., 1 to 2×10^{-9} mol/L), providing evidence that the binding sites examined are the biologically active receptors.

It has repeatedly been shown in pregnant adult animals that the binding capacity of the angiotensin II vascular smooth-muscle receptor responds in a reciprocal manner to changes in plasma angiotensin II.22, 23 Thus it would have been anticipated that down-regulation or increased occupancy of the angiotensin II vascular smooth-muscle receptor occurs during ovine pregnancy because plasma angiotensin II levels are normally increased. 8,9 Support for this conclusion, however, has previously been obtained primarily from studies of nonvascular smooth muscle15, 16 such as myometrium, which in nonpregnant animals responds to changes in plasma angiotensin II in a manner similar to vascular smooth-muscle receptor.28, 24 Although decreases in myometrial receptor-binding capacity were observed in the rat15 and sheep16 late in pregnancy, Paller⁷ observed no change in the angiotensin II-binding capacity in bladder smooth muscle of pregnant rats. Because the pregnant rat was used in the study of both tissues, it is evident that differences in receptor modulation in response to alterations in plasma angiotensin II exist in different types of smooth muscle. Similar observations have been made between the vascular smooth-muscle receptor and the adrenal glomerulosa, the latter of which exhibits parallel rather than reciprocal changes in binding capacity in the presence of elevated plasma angiotensin II.23, 24 There also may be important differences between species in the regulation of these nonvascular angiotensin II receptors. Therefore it might be suggested that the observations of Baker et al.25 of down-regulation of platelet angiotensin II receptors in gravid women also may not reflect alterations in vascular smooth-muscle receptor. Thus only the data of Brown and Venuto,26 who reported decreases in receptor density in the mesenteric artery of pregnant rabbits, can be directly compared with our data. Because we observed no pregnancy-associated differences in receptor-binding characteristics in the three arteries studied, it is possible that the discrepancy between our data and those of Brown and Venuto reflect species differences in receptor regulation.

The observed association between decreased systemic pressor responses and an unaltered binding capacity for angiotensin II vascular smooth-muscle receptor in the presence of elevated plasma angiotensin II levels in pregnancy may be novel. It is possible that in the sheep the vascular smooth-muscle receptor does not respond to alterations in plasma angiotensin II. However, we have shown in nonpregnant ewes that in-

creased responsiveness to infused angiotensin II occurs after volume expansion,8 and Blair-West et al.5 have reported decreased responses in salt-depleted non-pregnant and pregnant ewes. Furthermore, treatment with angiotensin-converting enzyme inhibitors increases the pressor response to infused angiotensin II in pregnant ewes. Although these data suggest that the angiotensin II vascular smooth-muscle receptor in sheep is responsive to alterations in plasma levels of the peptide, this has not been documented in direct studies of the vascular smooth-muscle receptor. Alternatively, the plasma levels of angiotensin II normally achieved in ovine pregnancy may not be sufficient to down-regulate the receptor. This too has not been studied.

If the angiotensin II vascular smooth-muscle receptor is not down-regulated in ovine pregnancy, how is receptor-binding capacity maintained in the presence of elevated plasma angiotensin II? Schiffrin et al.27,28 have reported that in adult male rats either the mesenteric angiotensin II vascular smooth-muscle receptor is up-regulated or down-regulation is prevented when elevation in plasma angiotensin II concentrations occur concomitantly with increased plasma levels of aldosterone or deoxycorticosterone or both. This may be applicable to the condition of pregnancy because elevated plasma levels of these mineralocorticoids occur in normal pregnancy,1,29 likely reflecting the relative underfilling associated with this condition and thus the need to retain sodium and water. It may be suggested that during pregnancy there is a need to maintain not only vascular tone in the presence of substantial systemic vasodilation but also vascular volume, which permits the increases in cardiac output that occur during pregnancy.3 Theoretically both can be achieved by activation of the renin-angiotensin system, which would result in increased secretion of mineralocorticoids and up-regulation or maintenance of the angiotensin II vascular smooth-muscle receptor by mechanisms not yet understood.

Alternative explanations for the maintenance of angiotensin II vascular smooth-muscle receptor binding in the face of elevated plasma angiotensin II levels may reside in other hormonal changes that occur during normal pregnancy. Plasma estrogen concentrations are increased during ovine pregnancy,30 primarily reflecting placental production. In studies of cycling rats, myometrial angiotensin II receptor binding increased fourfold during proestrus, when the plasma estrogen/progesterone ratio was high, and decreased during diestrus, when the estrogen/progesterone ratio was low.31 In neither instance was receptor affinity altered. Ovariectomy resulted in a decrease in myometrial angiotensin II receptors that was reversed by estrogen administration.8 Furthermore, progesterone inhibited this effect of estrogen. Similarly, estrogen administered

to pregnant rats caused a threefold increase in plasma angiotensin II, but no change in placental angiotensin II binding density, and progesterone-induced decreases in placental binding were inhibited by simultaneous administration of estrogen.32 Thus estrogen may participate in up-regulating or maintaining angiotensin II receptor binding capacity. We have observed in nonpregnant sheep that acute short- or long-term estrogen treatment increases plasma angiotensin II38 and is associated with attenuated pressor responses to infused angiotensin II.33,34 However, we have not yet examined the angiotensin II vascular smooth-muscle receptor to determine whether observations similar to those in the pregnant rat can be made in the ewe.

If the angiotensin II vascular smooth-muscle receptor is not down-regulated in pregnancy, another explanation must be sought for the refractoriness to this vasoconstrictor during pregnancy. In pregnant ewes,35 human beings, and several other species36, 37 there is evidence of increased production of vasodilator prostanoids, and vasoconstrictor responses to infused angiotensin II are increased after cyclooxygenase inhibition.³⁸ Furthermore, prostacyclin production by uterine arteries from pregnant sheep³⁹ is enhanced by angiotensin II through a receptor-mediated mechanism. Thus vasodilator prostanoids may antagonize the effects of angiotensin II, especially in the uteroplacental vascular bed. More recently we have reported that protein kinase C activity in the uterine artery decreases during ovine pregnancy and may be related to an increase in the estrogen/progesterone ratio.30 This too could account in part for the attenuated vasoconstrictor responses. Moreover, because angiotensin II stimulates protein kinase C activity, this effect of estrogen may explain how estrogen can maintain angiotensin II receptor-binding capacity in the face of increased plasma levels of angiotensin II32 and yet not be associated with an increase in vasoconstrictor responses.33,34 This, however, requires further study. Finally, at least two angiotensin II receptor subtypes have recently been described.40 It is possible that during pregnancy the maintenance of vascular smooth-muscle receptor binding capacity reflects increased expression of the AT2 nonvascular receptor in vascular smooth muscle, the action of which is not mediated through calcium and is not involved with contraction, and a decreased expression of the AT₁ vascular receptor. This also would explain the attenuated vascular responses to infused angiotensin II in the absence of down-regulation.

In summary, we have shown that during normal ovine pregnancy there is no evidence of decreased angiotensin II receptor-binding capacity or affinity in the vascular smooth muscle in three different arteries, suggesting that the attenuated vascular responses to this peptide in the systemic and uteroplacental vascular beds during pregnancy do not reflect receptor downregulation. It is more likely that this is caused by a series of rather complex interactions that may include the effects of the steroid hormones on the receptor itself, receptor signaling, the antagonistic effects of vasodilator prostanoids, and possibly the increased expression of the "nonvascular" receptor subtype in vascular smooth muscle.

We thank Mr. David Durham for his skilled technical assistance, Dr. Michael Fant for his help in establishing the binding studies, and Mrs. Susan Battle-Brown for her assistance in the preparation of the manuscript.

Regulation of corticotropin responsiveness in human fetal adrenal cells

William E. Rainey, PhD, Jan M. McAllister, PhD, E. William Byrd, PhD, J. Ian Mason, PhD, and Bruce R. Carr, MD

Dallas, Texas

The human fetal adrenal gland exhibits a high rate of steroidogenesis during fetal development and produces the majority of steroids used by the placenta for estrogen synthesis. Corticotropin appears to be the principal hormonal regulator of steroidogenesis in the fetal adrenal gland. However, little is known concerning the regulation of corticotropin receptors. In this study we examined the long-term regulation of corticotropin responsiveness as measured by the ability of human fetal adrenal gland cells to produce cyclic adenosine monophosphate after corticotropin treatment for 3 hours. We also examined the regulation of corticotropin receptors as determined by iodine 125-labeled corticotropin binding to fetal adrenal cells. Fetal adrenal glands were obtained from second-trimester abortuses. The two distinct zones of the fetal adrenal gland, the definitive zone and the fetal zone, were separated and the tissue mechanically dispersed. Freshly isolated cells responded to corticotropin with a sevenfold to tenfold increase in the production of cyclic adenosine monophosphate, indicating a functional corticotropin receptor-adenylate cyclase coupling. However, when either fetal zone or definitive zone cells were grown and passed in monolayer culture, corticotropin stimulation of cyclic adenosine monophosphate production dropped to only twofold. The loss of corticotropin stimulation of cyclic adenosine monophosphate production occurred with a loss of the steroid-metabolizing enzyme 17α-hydroxylase (P-450_{17a}). Because P-450₁₇₄ expression can be stimulated after treatment of fetal adrenal gland cells with corticotropin or forskolin, we attempted to increase the ability of corticotropin to stimulate cyclic adenosine monophosphate production in a similar manner. After cells were pretreated with corticotropin (0.1 to 100 nmol/L) or forskolin (0.1 to 100 μmol/L) for 4 days, their ability to produce cyclic adenosine monophosphate in response to corticotropin was examined. Pretreatment with both corticotropin and forskolin caused a dosedependent increase in the ability of corticotropin to stimulate the production of cyclic adenosine monophosphate. Cells stimulated with corticotropin after pretreatment with forskolin exhibited a 35- to 50-fold increase in cyclic adenosine monophosphate production compared with ncntreated cells (=twofold). Corticotropin pretreatment increased responsiveness to a lesser extent than forskolin pretreatment. The increase in corticotropin responsiveness occurred along with ar induction of P-450_{17a} enzyme levels. The effect of pretreatment with corticotropin and forskolin on the binding of iodine 125-labeled corticotropin to definitive zone cells was also investigated. Corticotropin pretreatment increased corticotropin receptor binding 2.8 times; forskolin pretreatment increased corticotropin binding by seven times. These data indicate that corticotropin responsiveness and corticotropin receptors in human fetal adrenal cells are regulated by a cyclic adenosine monophosphate-dependent mechanism. This observation is similar to findings in bovine and ovine adrenal cells where the number of corticotropin receptors is increased by corticotropin or cyclic adenosine monophosphate treatment. (AM J OBSTET GYNECOL 1991;165:1649-54.)

The human fetal adrenal gland is characterized by hyperplasia and high levels of steroid production. The diminished adrenal gland size in anencephalic fetuses and reduced fetal adrenal gland steroidogenesis after fetal exposure to exogenous glucocorticoid suggest that fetal pituitary corticotropin is one factor essential to normal adrenal gland development and function. A number of laboratories have made use of in vitro models to determine the mechanism by which corticotropin controls human fetal adrenal gland function. Dispersed

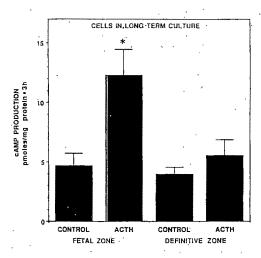

Fig. 1. Corticotropin (ACTH) responsiveness; freshly isolated cells versus cells in long-term monolayer culture. Definitive zone and fetal zone cells were treated for 3 hours with corticotropin (100 nmol/L). Medium content of cAMP was determined by radioimmunoassay. Values represent mean \pm SD for four different dishes of cells. Asterisk, Values significantly different from respective control value (p > 0.001).

cells have been useful for examination of the acute effects of corticotropin treatment.^{3,4} Studies of primary cultures of human fetal adrenal cells have been useful in defining the chronic role of corticotropin in regulating adrenal cell differentiation. Fetal adrenal cells grown in culture exhibit decreased steroid hormone production as well as reduced levels of steroid-metabolizing enzymes. Corticotropin treatment of these cells increases steroidogenesis and the expression of steroid-metabolizing enzymes.^{5,9} Thus both in vivo and in vitro evidence suggests a key role of corticotropin in maintaining fetal adrenal cell steroidogenic capacity.

The ability of adrenal cells to respond to corticotropin treatment depends on the ability of this peptide to stimulate production of cyclic adenosine monophosphate (cAMP). Recent evidence obtained with adult ovine and bovine adrenal cells suggests that corticotropin responsiveness is regulated in a cAMP-dependent manner.10.11 However, little is known about corticotropin receptor regulation in human fetal adrenal cells. Previous reports have shown that human fetal adrenal cells do not undergo desensitization after corticotropin treatment but actually show increased responsiveness after long-term corticotropin stimulation.9 In this study we examined the effects of chronic treatment with corticotropin and forskolin on corticotropin responsiveness. Our data give strong support to the hypothesis that corticotropin is able to increase expression of its own receptor level in human fetal adrenal cells.

Material and methods

Cell preparation. Fetal adrenal glands were obtained from second-trimester (12 to 18 weeks' gestation) human abortuses delivered electively by dilation and ex-

traction. The tissues were obtained under the auspices of the Donors Anatomical Gift Act of the State of Texas after obtaining written consent from the women having the abortions. The consent form and the experimental protocol were approved by the Human Research Review Committee of the University of Texas Southwestern Medical Center at Dallas.

After separation of the fetal and the definitive zones, the adrenal glands were minced finely and placed in Hanks' Ca2+- and Mg2+-free medium that contained N-2-hydroxyethylpiperazine-N-2-ethanesulfonic acid (HEPES) buffer (25 mmol/L, pH 7.4). The tissue fragments were dispersed by repeated aspiration and expulsion with a 5 ml plastic pipette at room temperature. The dispersed tissue was filtered through gauze to remove the remaining fragment aggregates, and the filtrate was centrifuged at 800g for 10 minutes. For experiments with freshly dispersed cells, the pellet was resuspended in Ham's F-12-Dulbecco's modified Eagle's medium and treated immediately. For monolayer culture the cells were suspended in Ham's F-12-Dulbecco's modified Eagle's medium containing 5% horse serum, 5% fetal bovine serum, and 1% antibiotics-antimycotics and plated at a density of 5×10^6 cells per 75 cm² flask. The cells were allowed to attach to the plastic dish for 24 hours; thereafter the medium (20 ml per dish) was replaced every 48 hours. The cells were maintained in this medium in a humidified atmosphere of carbon dioxide (5%) and air (95%) at 37° C. At confluency (7 to 10 days) the cells were subcultured with a trypsin-ethylenediaminetetraacetic acid solution (Sigma Chemical Co., St. Louis) onto five flasks (75 cm²) and allowed to grow to confluency, when they were trypsinized, placed in vials, and stored frozen in

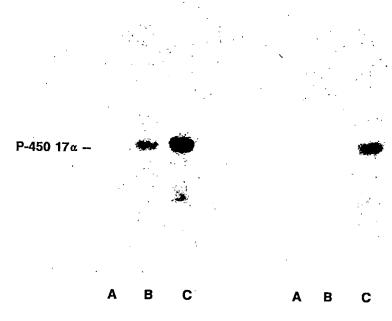

Fig. 2. Regulation of P-450_{17a} enzyme expression in definitive zone (right) and fetal zone (left) cells maintained in culture for 3 to 4 weeks. Cells were then treated with either corticotropin (10 nmol/L) or forskolin (10 μ mol/L). Immunoblotting analysis was carried out on 100. μ g of total cell protein for P-450_{17a}. A, Control; B, corticotropin; C, forskolin.

liquid nitrogen. For each experiment one vial of cells was unthawed and cultured in 12-well dishes. Cells were maintained in culture for a total of 3 to 4 weeks before the experiments.

Immunoblotting. After treatments, cells were washed with 0.9% sodium chloride solution and removed in a small volume of lysing buffer as previously. described.12 One-dimensional electrophoresis was performed in a 12% polyacrylamide gel with a gel system (Precast, Amersham, Arlington Heights, Ill.). Sample buffer contained 0.05 mol/L Tris (pH 6.8), 2% sodium dodecyl sulfate, 10% glycerol, and 8 mmol/L ethylenediaminetetraacetic acid; samples were loaded after boiling for 3 minutes in the presence of 2-mercaptoethanol. Electrophoresis was carried out at 30 V at room temperature. Proteins were transferred to a nitrocellulose paper in an electrophoresis unit (Transphor, Hoefer Scientific Instruments, San Francisco) at 100 V for 1 hour at 2° to 4° C in a buffer containing 20% methanol, 20 mmol/L Tris, and 150 mmol/L glycine. The nitrocellulose membrane was incubated for 15 minutes at room temperature in a blocking buffer containing 10 mmol/L Tris, pH 7.4, 0.15 mol/L sodium chloride, 0.2% Nonidet P-40, and 0.5% dry milk and placed for 2 hours in the same buffer containing polyclonal antibodies (10 µg immunoglobulin G per milliliter) against human placental 3β-hydroxysteroid dehydrogenase or pig testis P-450_{17a}. Membrane blots were washed in the same buffer without antibody for 15 minutes and then incubated in the blocking buffer containing approximately 106 cpm/ml of iodine 125labeled protein A (ICN Biochemicals, Irvine, Calif.) for

30 minutes. Finally the nitrocellulose membrane was washed in blocking buffer for 1 hour before exposure to photographic film. All incubations and washings were performed at room temperature.

Cyclic adenosine monophosphate determinations. The measurement of cAMP was quantified in the culture medium with radioimmunoassay kits (Advanced Magnetics, Cambridge, Mass.). For each assay the acetylated procedure for increased sensitivity was used. Standard curves for cAMP were constructed in the incubation medium and acetylated therein. The preparation of standards in incubation medium increased assay sensitivity. Extraction of the medium was not necessary. Statistical differences were determined with one-way analysis of variance and Newman-Keuls multiple comparison analysis.

Corticotropin binding. Experiments were performed on 12-well plates containing approximately 105 cells per well. For binding studies the human fetal adrenal cells were treated in a medium containing 2% Ultraser G (IBF Biotechnics, Villeneuve-la-Garenne, France). Culture with this medium supplement was found to increase corticotropin binding to human fetal adrenal cells. Cells were washed four times with medium composed of Dulbecco's modified Eagle's-F-12 medium plus HEPES (15 mmol/L, pH 7.4). Binding assays were carried out for 1 hour at room temperature as described previously. 10-12 In brief, 0.5 ml of binding medium (Dulbecco's modified Eagle's-F-12 medium; 0.5% bovine serum albumin; 0.1% bacitracin; 15 mmol/L HEPES containing 125 I-tyrosine 23-human corticotropin 1-39 (\approx 200,000 cpm per well \approx 60 fmol per

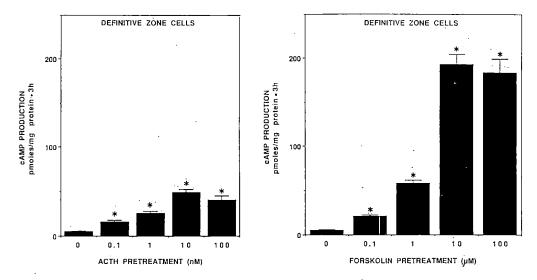

Fig. 3. Regulation of corticotropin (ACTH) responsiveness. Definitive zone cells were maintained in culture for three to four wells, then treated with indicated concentration of corticotropin or forskolin for 4 days. Cells were rinsed and treated with corticotropin (10 nmol/L) for 3 hours. Medium content of cAMP was determined by radioimmunoassay. Values represent mean \pm SD for four different dishes of cells. well) was used. ¹²⁵Í-tyrosine 23 human corticotropin 1-39 (specific activity of 1900 Gi/mmol or 70 TBq/mmol) was obtained (Amersham, Arlington Heights, Ill.). The nonspecific binding was determined with unlabeled corticotropin 1-24 (1 × 10⁻⁶ mol/L) and represented 5% to 10% of the total bound. At the end of incubation plates were placed on ice and cells were washed four times with medium (Dulbecco's modified Eagle's–F-12 medium containing HEPES, 15 mmol/L, pH 7.4) at 4° C. The cell layer was then lysed in 0.4% deoxycholate, and radioactive lysates were counted in a gamma radiation spectrometer.

Results

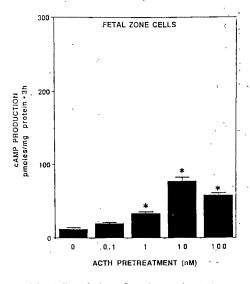

To examine human fetal adrenal cell responsiveness to corticotropin we examined the ability of both definitive zone and fetal zone cells to produce cAMP after treatment with corticotropin for 3 hours. Freshly isolated definitive zone and fetal zone cells responded to corticotropin (100 nmol/L) treatment with a 7- to 10-fold increase in cAMP production (Fig. 1). When these cells were maintained in culture for 3 to 4 weeks there was a decline in response to corticotropin. Specifically, definitive zone and fetal zone cells not only decreased the amount of cAMP produced after corticotropin treatment but responded with only a 1.5- to 2.5-fold increase of cAMP production above base levels.

The decline in corticotropin responsiveness appeared to be similar to the loss of steroid-metabolizing enzymes seen in these cells maintained in long-term culture. Definitive zone and fetal zone cells maintained for 3 to 4 weeks in culture exhibited nondetectable levels of immunoreactive P-450_{17a} (Fig. 2). Treatment

of these cells with corticotropin (10 nmol/L) or forskolin (10 μ mol/L) for 4 days caused expression of P-450_{17a}. The induction of enzyme expression after treatment with forskolin was greater in both fetal zone and definitive zone than when corticotropin was used.

To see whether responsiveness could be regained in a manner similar to that with P-450_{17α}, we treated fetal zone and definitive zone cells for 4 days with corticotropin (0.1 to 100 nmol/L). After treatment, cells were washed four times to remove residual corticotropin and then treated with corticotropin (100 nmol/L) for 3 hours. Fetal zone and definitive zone cells pretreated with corticotropin were more responsive to acute stimulation of cAMP production (Figs. 3 and 4). Corticotropin pretreatment caused a concentration-dependent increase in the ability of corticotropin to stimulate cAMP production. Significant effects of corticotropin pretreatment were observed at a concentration of 1 nmol/L. Forskolin pretreatment also increased definitive zone and fetal zone responsiveness to corticotropin (Figs. 3 and 4). The ability of forskolin pretreatment to increase corticotropin responsiveness was more pronounced than that seen after corticotropin pretreatment.

We examined the effects of chronic treatment with corticotropin or forskolin on corticotropin receptors (Fig. 5). Definitive zone cells were treated for 4 days with corticotropin (10 nmol/L) or forskolin (10 µmol/L). Relative changes in corticotropin receptors were determined by examining binding of ¹²⁵I-tyrosine 23 human corticotropin 1-39. Binding increased 2.8 times after corticotropin pretreatment and seven times after forskolin pretreatment.

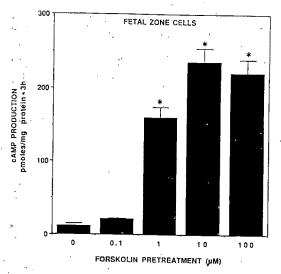

Fig. 4. Regulation of corticotropin (ACTH) responsiveness. Fetal zone cells were maintained in culture for 3 to 4 weeks, then treated with indicated concentrations of corticotropin or forskolin for 4 days. Cells were rinsed and stimulated with corticotropin (100 nmol/L) for 3 hours. Medium content of cAMP was determined by radioimmunoassay. Values represent mean \pm SD for four different dishes of cells. Asterisk, Values significantly different from controls (p > 0.001).

Comment

This report constitutes the first examination of the regulation of human fetal adrenal cell responsiveness to corticotropin. Our findings demonstrate that responsiveness to corticotropin is lost when both fetal zone and definitive zone cells are maintained in long-term culture. Responsiveness was, however, regained when the cells were treated with corticotropin or forskolin. These data support the hypothesis that corticotropin receptors and responsiveness, like the induction of steroid-metabolizing enzymes, are regulated in a cAMP-dependent manner.

Human fetal adrenal cells have been extensively used to examine the regulation of steroid hormone production.³⁻⁹ With time in culture these cells exhibit a decline in base levels of steroid production and expression of steroid-metabolizing enzymes. The loss of these functions is believed to be caused by the removal of the cells from a source of corticotropin. Treatment with corticotropin will stimulate steroidogenesis and the expression of several steroid-metabolizing enzymes.⁵⁻⁹ Various detailed studies have demonstrated that steroid production and the enzymes necessary for steroidogenesis are regulated in a cAMP-dependent manner.

In addition to the loss of steroid-metabolizing enzymes, bovine adrenal cells in culture have been shown to exhibit a reduced ability to respond to corticotropin.¹³ The simultaneous loss of both corticotropin response and steroidogenic enzymes suggests that these events might be regulated in a similar manner. To address this question definitive zone and fetal zone cells were grown for 3 to 4 weeks in monolayer cell culture,

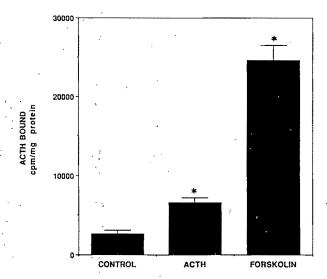

Fig. 5. Regulation of 125 I-corticotropin (ACTH) binding to definitive zone cells maintained in culture for 3 to 4 weeks, then treated with corticotropin (10 nmol/L) or forskolin (10 μ mol/L) for 4 days. Cells were rinsed and 125 I-corticotropin binding examined. Values represent mean \pm SD for specific binding to four separate dishes of cells. For corticotropin binding studies cell culture medium was supplemented with Ultraser G. This medium supplement was found to increase 125 I-corticotropin binding. Asterisk, Values significantly different from control (p > 0.001).

after which corticotropin stimulation of cAMP production was examined. In agreement with reports in which bovine adrenal cells were used, human fetal adrenal cells maintained in long-term cell culture exhib-

ited a reduced response to corticotropin. To determine whether responsiveness was regulated in a manner similar to that of steroid-metabolizing enzymes we treated cells for 4 days with either corticotropin or forskolin. The expression of P-450_{17α} was markedly enhanced by both factors. In addition the responsiveness to corticotropin was increased by both corticotropin and forskolin. This effect is similar to that seen in bovine adrenocortical cells where corticotropin treatment can increase the ability of the cells to respond to corticotropin. ¹⁰

The mechanism by which corticotropin stimulates cyclic adenosine monophosphate production is complex and relies on the expression of corticotropin receptors, guanosine triphosphate-binding proteins, and adenylate cyclase. To determine whether corticotropin receptor expression was increased in human fetal adrenal cells, we examined the binding of 125 I-corticotropin to definitive zone cells. Both corticotropin and forskolin increased binding of 125I-corticotropin (Fig. 5). The ability of corticotropin to increase corticotropin receptor expression has also been demonstrated in cultures of adult bovine and ovine adrenal cells.10,11 Corticotropin also appears to increase the expression of guanosine triphosphate-binding proteins in bovine adrenal cells.14 Thus corticotropin treatment of adrenal cells may act to up-regulate the corticotropin receptor and coupling system.

These data support the hypothesis that corticotropin is a positive regulator of its own responsiveness. The positive effect of corticotropin on its own receptor may have physiologic significance. In the fetal adrenal gland corticotropin receptor expression could be regulated by plasma corticotropin levels. Previously we have shown that corticotropin activation of adenylate cyclase is low in the anencephalic fetal adrenal gland where circulating levels of corticotropin are low. 15 In the ovine and goat fetus the ability of fetal adrenal cells to respond to corticotropin appears to parallel the fetal plasma levels of corticotropin. 16-18 Such data suggest that enhanced glucocorticoid levels observed in response to chronically elevated plasma corticotropin are related to at least two effects: (1) a positive trophic effect on the expression of several steroid-metabolizing enzymes and (2) a positive trophic effect of corticotropin on its own receptor.

We appreciate the technical assistance of Nora Cline.

The metabolic clearance rate of epinephrine in the fetus of the diabetic ewe

Jan E. Dickinson, MD, Bruce A. Meyer, MD, Susie Chmielowiec, MS, and Sue M. Palmer, MD

Houston, Texas

Delayed organ maturation is a characteristic of the fetus of the diabetic mother with poor glucose control. We hypothesized that the ovine fetal catecholamine maturation sequence would be delayed in the fetus of the diabetic ewe. Twelve pregnant ewes were rendered glucose intolerant by the administration of streptozocin at 85 to 95 days' gestation. Maternal diabetic status was verified with fasting blood glucose assessments. The fetal metabolic clearance rate of epinephrine was determined at 126 to 140 days' gestation by the constant infusion of 0.1 µg epinephrine per kilogram estimated feta weight per minute. Fetal arterial blood gas values, lactate, glucose, and insulin levels were measured before infusion; after 20, 30, and 40 minutes of epinephrine infusion; and 15, 30, and 60 minutes after cessation of infusion. Fetal plasma glucose rose significantly from a control level of 42.1 ± 8.2 to 64.6 ± 5.9 mg/dl during the epinephrine infusion (p < 0.05). Fetal insulin levels increased from a baseline of 9.2 \pm 2.6 μ IU/ml to 32.4 \pm 18.0 in the recovery period (p < 0.05), and lactate levels similarly rose from 36.4 \pm 4.8 to 52.2 \pm 8.2 mg/dl (p < 0.05). The plasma epinephrine production rates did not vary significantly between fetuses <135 and >135 days' gestation (15.4 \pm 1.5 vs 13.9 \pm 2.0 ng/min, p > 0.5). The fetal metabolic clearance rate of epinephrine at early gestations (<135 days) was similar to that of the fetus of the nondiabetic ewe (35.3 \pm 3.4 vs 28.0 \pm 4.3 ml/min/kg, p > 0.2). However, at later gestations (>135 days) the fetus of the diabetic ewe did not have the increase in the metabolic clearance rate previously published for the control fetus (32.0 \pm 4.6 vs 133.7 \pm 41.7 ml/min/kg, p < 0.05). These data appear to indicate an absence in the maturation of the metabolic clearance rate of epinephrine in the fetus of the diabetic ewe. The observed alteration in the metabolic clearance rate of epinephrine of the fetus of the diabetic ewe could potentially impair the response to stress. (AM J OBSTET GYNECOL 1991;165:1655-60.)

Key words: Ovine, diabetes, fetus, catecholamines, metabolic clearance rate

There is a well-defined catecholamine maturation sequence in the ovine fetus. Comline and Silver¹ in 1966 stimulated the adrenal glands of fetal lambs and showed that before 80 days' gestation dopamine is the principal catecholamine secreted. Early in the third trimester norepinephrine appeared in response to adrenal stimulation, and during the last 20 days of gestation epinephrine replaced norepinephrine as the dominant stress catecholamine. The ovine fetal adrenal gland increases in size and weight as the fetus matures² and undergoes maturation before the completion of gestation.¹

It has previously been reported that the plasma epinephrine concentration decreases as gestation advances in the ovine fetus.³ The production rate of epinephrine is constant throughout gestation in this species.⁴ The

observed reduction in plasma epinephrine concentration is a secondary effect of an increase in the epinephrine metabolic clearance rate, which occurs at approximately 134 days' gestation.⁴

Delayed organ maturation is a characteristic of the fetus of the diabetic mother with poor glucose control. We hypothesized that the characteristic fetal epinephrine maturation sequence would be delayed in the fetus of the diabetic eye.

Material and methods

Twelve pregnant Western-bred ewes of known gestational age were rendered glucose intolerant by the intravenous administration of streptozocin (The Upjohn Co., Kalamazoo, Mich.) on two separate occasions, 4 days apart, commencing at 85 to 90 days' gestation. After an overnight fast, streptozocin was administered to the ewe at a dose of 50 mg/kg maternal weight. Immediately before injection, the streptozocin was reconstituted in 50 ml sterile 0.9% sodium chloride and then infused over 3 to 4 minutes through a maternal peripheral hind limb vein. To ensure active secretion of insulin and maximal degranulation of the pancreatic β-cells, the streptozocin was injected while the animals

were feeding. Maternal carbohydrate tolerance was assessed by serial fasting plasma glucose testing before and 4 to 6 weeks after streptozocin administration.

The ewes were transferred to the Animal Care Center at our institution at 112 to 120 days' gestation and acclimated for a minimum of 7 days before surgery. A diet of pelleted alfalfa and hay was fed to the ewes. The animals were maintained in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals' in the Animal Care Center of the University of Texas Medical School at Houston. The experimental protocol was approved by our institutional Animal Welfare Committee.

At 120 to 127 days' gestation, while the ewes were under general anesthesia, polyvinyl catheters were placed in the fetal dorsal aorta and vena cava through a dorsal pedal artery and vein. Catheters were also placed in the amniotic cavity and in a maternal lateral femoral circumflex artery and vein. The animals were allowed to recover for 5 to 7 days after surgery, at which time normal maternal and fetal arterial blood gas values were observed.

To evaluate the basal metabolic clearance rate of epinephrine, the experimental protocol consisted of a 10minute control period, a 40-minute intravenous fetal infusion of epinephrine (lot 75F-0226, Sigma Chemical Co., St. Louis), and a 60-minute recovery period. Maternal and fetal mean arterial pressure (MAP), fetal venous pressure, and amniotic cavity pressure were recorded continuously with a physiologic recorder (model R611, Beckman Instruments, Inc., Schiller Park, Ill.) and transducers (Statham model P23Db, Spectramed, Oxnard, Calif.). Maternal heart rate and fetal heart rate (FHR) were calculated from the arterial pulse every 5 minutes. Fetal arterial blood samples were collected for blood gas analysis and catecholamine, glucose, insulin, and lactate determinations at the beginning and end of the 10-minute control period; at 20, 30, and 40 minutes during the epinephrine infusion; and at 15, 30, and 60 minutes of recovery.

Epinephrine concentrations were measured in the infusate at the beginning and end of each infusion to detect accumulation of oxidative metabolites. The metabolic clearance rate was calculated from these measured epinephrine levels in the infusate. The infusate was prepared within 25 minutes of infusion from epinephrine standard dissolved at 0.9% normal saline solution with additional ethylene glycol-glutathione preservative. The epinephrine (0.1 μ g/kg estimated fetal weight) was infused at a rate of 0.1 ml/min into the fetal inferior vena cava by a pump (Harvard Apparatus Co., Millis, Mass.).

Fetal arterial blood gases were measured with a blood gas analyzer (model 158, Dow Corning Corp., Medfield, Mass.) at 39° C. The maternal and fetal plasma

glucose levels were assessed with a glucose analyzer (model 23A, Yellow Springs Instrument Co., Inc., Yellow Springs, Ohio). Plasma insulin, levels were assessed with a specific radioimmunoassay (ICN Micromedic Systems, Horsham, Pa.), and lactate levels were measured enzymatically (Sigma Diagnostics, St. Louis). Catecholamine samples were collected in chilled syringes, placed in iced tubes containing ethylene glycol-reduced glutathione, and centrifuged. The plasma was removed and stored in a -70° C freezer before assay. Plasma catecholamine levels were determined by electrochemical detection with a glassy-carbon electrode (model 460 electrochemical detector, Waters Chromatography Div., Millipore Corp., Milford, Mass.) after separation on a high-pressure liquid chromatography C18 column as previously described.6 The assay sensitivity was 1 to 2 pg/ml for epinephrine with an interassay variation of 7% and an intraassay variation of

By means of the constant infusion method, the metabolic clearance rate of epinephrine was determined by the formula of Tait and Burnstein⁷:

$$MCR = P/(Css - Cb)$$

where MCR is the metabolic clearance rate, P is the production rate or amount infused, Css is the steadystate plasma epinephrine levels, and Cb is the baseline plasma epinephrine level. All values are corrected for body weight. The constant infusion method requires two assumptions to be made because there is no isotope labeling of the infused compound. First, steady-state levels of the compound under investigation must be achieved in all compartments. This is presumed when the plasma concentration reaches a steady state. Second, it is assumed that the dosage of the infused compound does not alter basal homeostasis or metabolic clearance. In preliminary studies significant alterations in heart rate, MAP, and arterial pH were not observed with a dose of 0.1 µg epinephrine per kilogram of weight.

Statistical analysis was performed with the Student t test and analysis of variance. Logarithmic transformation [Log(x + I)] was used when variances were not equal. All data are mean \pm SEM. A probability of p < 0.05 was chosen to represent statistical significance.

Results

To document the induction of maternal diabetes, serial fasting plasma glucose assessments were performed. After streptozocin administration, the fasting venous plasma glucose values of the 12 ewes rose significantly from a pretreatment level of 78.1 ± 7.2 to 108.2 ± 6.1 mg/dl 4 to 6 weeks later, p < 0.05. Fasting maternal glucose levels were conducted on five nontreated late-gestation ewes housed in the Animal Care

Center at the time of our experimentation. These control plasma glucose levels were $71.4 \pm 7.1 \text{ mg/dl}$, demonstrating no tendency toward carbohydrate intolerance with advancing gestation in the ewe. We believe these results confirm the presence of diabetes in the streptozocin-treated ewes.

There was no significant alteration in FHR and MAP from control values during the period of the epinephrine infusion or recovery (Fig. 1). The baseline FHR was 162.9 ± 5.2 beats/min, which increased nonsignificantly at the completion of the infusion and throughout the recovery period to 169.3 ± 5.1 beats/min (p > 0.3). The baseline fetal MAP of 54.3 ± 3.0 mm Hg increased nonsignificantly during the epinephrine infusion to 57.7 ± 3.2 mm Hg (p > 0.2), returning to baseline levels in the recovery period.

Arterial blood gas data are shown in Fig. 2. There were no statistically significant changes in pH, Po₂ or PCO2 during the infusion or recovery periods. The fetal arterial pH showed a nonsignificant decrease from a baseline value of 7.36 \pm 0.01 to 7.34 \pm 0.01 after 20 minutes of epinephrine infusion (p > 0.1) and remained at this slightly lower level for the remainder of the study.

There was a significant elevation in fetal mean plasma glucose concentration during the epinephrine infusion (Fig. 3). From a baseline value of $42.1 \pm 8.2 \text{ mg/dl}$ the plasma glucose level rose to 65.5 ± 5.9 mg/dl after 30 minutes of infusion (p < 0.05). At the completion of the recovery period the fetal glucose concentration, although not statistically elevated from the control, had not returned to baseline values, being 52.6 ± 11.7 mg/dl (p > 0.4). The fetal mean plasma insulin concentration demonstrated a delayed rise after cessation of the epinephrine infusion. Control plasma insulin levels of 9.6 \pm 2.5 μ IU/ml decreased to 4.5 \pm 1.8 $\mu IU/ml$ (p > 0.1) after 20 minutes of epinephrine infusion and then rapidly increased to 32.4 ± 18.0 µIU/ml 15 minutes after cessation of the infusion (p < 0.05).

Fetal blood lactate levels progressively increased throughout the experimental period, reaching significantly elevated levels in the recovery period (Fig. 4). Baseline lactate values of $36.1 \pm 4.8 \text{ mg/dl}$ increased to $48.7 \pm 4.5 \text{ mg/dl}$ (p = 0.06) after 40 minutes of epinephrine infusion and peaked at 54.1 ± 5.7 mg/dl (p < 0.05) 30 minutes after cessation of the infusion.

The average basal epinephrine concentration was $435.7 \pm 36.0 \text{ pg/ml}$. We did not observe a marked decline in basal epinephrine concentration with advancing gestational age. The individual calculated epinephrine clearance rate values for the fetus of the diabetic ewe are plotted against gestational age in Fig. 5. Plasma catecholamine samples from two fetuses were inadver-

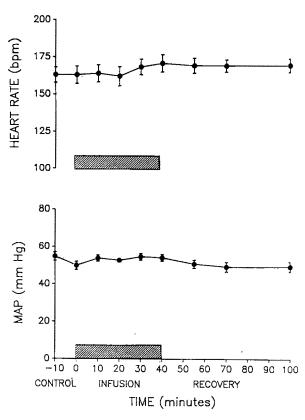

Fig. 1. FHR and MAP before, during, and after infusion of epinephrine 0.1 μ g/kg/min, n = 12. Data represent mean ± SEM.

tently lost during assay, and the data are available from 10 animals only. In the normal ovine fetus the epinephrine metabolic clearance increases as gestation advances.4 In the fetus of the diabetic ewe, however, there is no significant alteration in epinephrine clearance rate with increasing gestational age. In this species term is 150 ± 5 days' gestation. Because of difficulties in maintaining the preparation beyond 140 days' gestation, we were unable to obtain later studies.

Plasma epinephrine production rates were calculated by multiplication of the mean basal plasma epinephrine level by the individual metabolic clearance rate. Plasma epinephrine production rates remained constant relative to gestational age in the fetus of the diabetic ewe. The mean epinephrine production rate for study fetuses <135 days' gestation (n = 5) was 15.4 \pm 1.5 ng/min and did not differ from those of older fetuses (>135 days' gestation, n = 5) at 13.9 ± 2.0 ng/min (p > 0.5).

Comment

The catecholamine content of the ovine fetal adrenal gland increases progressively as gestational advances, plateauing at 130 to 140 days' gestation.2 The adrenal content of norepinephrine decreases, whereas that of epinephrine increases with gestation.1.2 The rise in epi-

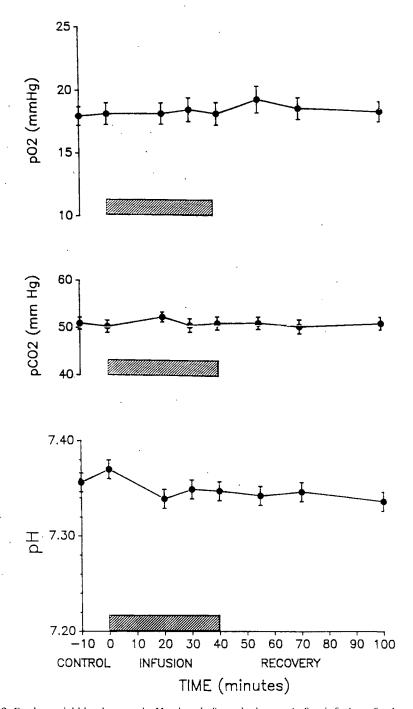

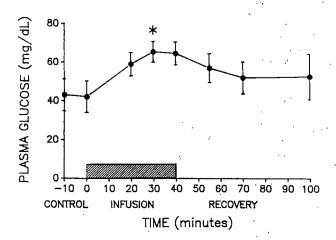

Fig. 2. Fetal arterial blood gas and pH values before, during, and after infusion of epinephrine 0.1 $\mu g/kg/min$, n=12. Data represent mean \pm SEM.

nephrine content is presumed to be a secondary effect of the increase in cortisol production in the adrenal cortex of the maturing fetus.'

With advancing gestation there is an increase in renal blood flow, glomerular filtration, and amniotic fluid concentration of catecholamines.^{8,9} This is suggestive of an increase in the renal clearance of catecholamines toward the end of gestation.

In the fetal lamb the plasma concentrations of catecholamines decrease with increasing gestational age³ although there is no alteration in catecholamine production rate.⁴ The decreased plasma catecholamine concentration coupled with the increase in amniotic fluid concentration implies increased clearance of these vasoactive agents with advancing gestation. It has been previously shown in the chronically catheterized nor-

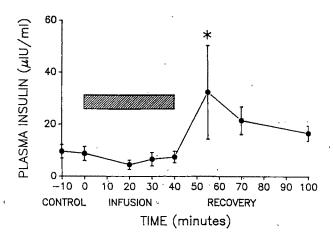

Fig. 3. Fetal plasma glucose and insulin levels before, during, and after infusion of epinephrine 0.1 μ g/kg/min, n = 12. Data represent mean \pm SEM. Asterisk, p < 0.05.

mal ovine fetus that the metabolic clearance rate of epinephrine is gestation dependent, with a rapid maturation in clearance after 134 days' gestation.⁴

The fetus of the diabetic woman with poor glucose control classically demonstrates delayed organ maturation, most typified by a retardation of pulmonary function. 10,11 Fetal lung maturation is influenced by several hormones, including cortisol, thyroxine, triiodothyronine, prolactin, and insulin.12-14 Parket et al.15 reported a reduction in the umbilical serum concentrations of cortisol in infants of women with diabetes in whom respiratory distress syndrome developed. Saltzman et al.16 noted a decrease in the umbilical cord prolactin concentration of infants of diabetic mothers. Cortisol acts as an inducer of fetal enzyme activity, and catechol-O-methyltransferase activity may potentially be impaired in the fetus of the diabetic mother, resulting in a reduction in clearance of released catecholamines. We hypothesized that as a marker of organ immaturity the metabolic clearance rate of epinephrine would be delayed in the fetus of the diabetic ewe.

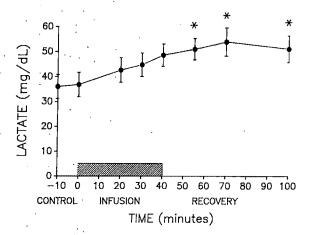

Fig. 4. Fetal blood lactate levels before, during, and after infusion of epinephrine $0.1 \,\mu\text{g/kg/min}$, n=12. Data represent mean \pm SEM. Asterisk, p < 0.05.

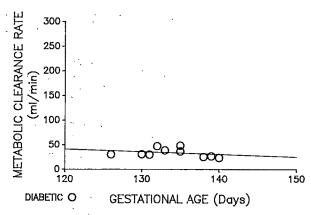

Fig. 5. Epinephrine metabolic clearance rate versus gestational age in fetus of diabetic ewe, n = 10. Data represent mean \pm SEM.

'An absence of maturation of epinephrine clearance in the fetus of the diabetic ewe throughout the gestations examined has been shown. Unfortunately, the animal model limited the number of animals evaluated at very early and late gestational ages. We speculate that the fetal epinephrine metabolic clearance rate increases later in gestation in the diabetic ewe, with the attainment of values equivalent to those of Palmer et al.4 and Padbury et al., 17 but were technically unable to continue our preparations beyond 140 days. Possible solutions to this question could be to perform clearance studies on the lambs immediately after birth, although this would entail separating the lamb from the ewe, thereby removing the lamb from its physiologic condition and invalidating the method. Another alternative is to administer thyroxine or corticosteroids in utero to the fetal lamb and repeat the metabolic clearance rate studies to assess if maturation can be induced. Cortisol is believed to activate the synthesis of epinephrine in the adrenal medulla by inducing the activity of the enzyme phenylethanolamine-N-methyltransferase. Because Parker et al. noted in humans an association between neonatal respiratory distress syndrome and the degree of maternal hyperglycemia, the clearance studies could be repeated with strict control of maternal hyperglycemia.

We attempted to assess the metabolic clearance rate of epinephrine in a basal physiologic state but were only partially successful. There were no significant alterations in FHR, MAP, or arterial pH; however, there were significant increases in plasma glucose and blood lactate levels with suppression of plasma insulin during epinephrine infusion, followed by rebound hyperinsulinemia. It is probable that there was significant peripheral vasoconstriction in spite of no significant alteration in measured fetal cardiovascular parameters. This would account for the rise in lactate. This effect has been observed in previous investigations with the constant infusion method.4, 17, 19 It would be worthwhile to conduct similar studies with lower epinephrine infusion concentrations to assess the physiologic thresholds for the metabolic effects of epinephrine in the ovine fetus.

We present the first examination of catecholamine clearance mechanisms in an ovine diabetic model. There appears to be a delay in the fetus of the diabetic ewe to clear epinephrine. This alteration may be a secondary effect of a generalized delay in organ maturation that has been observed in infants of mothers with uncontrolled hyperglycemia. We speculate that an inability to clear stress-released epinephrine may reduce the ability of such fetuses to tolerate stress.

We thank Wil Morgan and The Upjohn Co. for their support of this research.

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: Evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis

Brent E. Finley, MD, and Stata Norton, PhD

Kansas City, Kansas

Congenital malformations are the leading cause of the increased perinatal mortality in the infants of insulin-dependent diabetic mothers. The mechanisms(s) of diabetic teratologic development has yet to be defined. Hyperglycemia is known to depress aerobic metabolism in many organisms and cell lines. Reid hypothesized that exposure to hyperglycemia could result in decreased mitochondrial biogenesis in embryonic cells. Should these cells suddenly be changed to an environment of lower glucose concentration, decreased energy capabilities would exist until sufficient numbers of mitochondria could be regenerated. Such cells may not be capable of meeting temporal-spatial requirements, thereby resulting in structural abnormalities. In our study the explanted rat embryo model demonstrated that in the head-fold region hyperglycemia produced morphologic alterations of mitochondria but no difference in the number of mitochondria per cell. Specifically, embryos cultured in euglycemia demonstrated orthodox mitochondrial configuration, whereas those cultured in hyperglycemia had mitochondria in a condensed configuration. These findings were reversible. A modification of Reid's original hypothesis may provide an explanation for the mechanism of diabetic teratologic development. (AM J OBSTET GYNECOL 1991;165:1661-6.)

Key words: Congenital malformations (diabetic), mitochondria (morphology), hyperglycemia

Congenital malformations remain the major factor in the increased perinatal mortality experienced by the infants of insulin-dependent diabetic mothers. These malformations affect numerous organ systems and have a wide range of expression. It is therefore argued that the teratogenic agent acts early in gestation at the cellular level in a universal manner. Because the exact teratogenic mechanism remains undefined, hyperglycemia continues to be implicated in the teratogenic process of this common maternal metabolic disorder. 5-5

One of the problems in elucidating the mechanism(s) resulting in the malformations is the myriad of metabolic, hormonal, and substrate alterations evidenced in insulin-dependent diabetics. The explanted rat embryo model allows the investigator to accurately control and

manipulate the environment of the developing embryo.⁶ The head-fold region of the developing rat embryo has been demonstrated to be especially sensitive to environmental alterations. Failure of closure of the anterior neuropore has served as a morphologic marker for teratogenic effects.^{7, 8}

Extreme fluctuations in maternal glucose levels are not uncommon in pregnancies complicated by insulindependent diabetes. On the basis of metabolic studies in yeast and some cell cultures, Reid9 hypothesized that sudden swings in glucose levels could be more teratogenic than constant hyperglycemia. Specifically, cells exposed to hyperglycemia are known to switch to anaerobic metabolism. This alteration in metabolic activity is described as the Crabtree effect and is well documented in the literature. 10-13 Reid hypothesized that this metabolic switch resulted in a down-regulation in mitochondrial biogenesis, as evidenced in studies in crabtree-positive yeast. 10-13 Should a cell exposed to hyperglycemia and functioning in an anaerobic fashion be suddenly changed to a euglycemic environment, Reid went on to hypothesize, there would be a time interval before adequate mitochondrial numbers had been regenerated so as to allow for adequate energy production to meet cellular demands. This time interval was designated as the energy gap. Should such an energy gap exists in an embryonic cell with a set program for development, the cell might not be able to meet its

6/6/33420

spatiotemporal requirements, with the result being a fetal anomaly, e.g., failure of proper closure of the anterior neuropore with resultant anencephaly. This specific lesion has been demonstrated to be 10 times more common in infants of diabetic mothers¹⁴ than in infants of nondiabetic mothers. Anterior neuropore defects, including failure of closure and abnormal closure, are a common malformation in rat embryos cultured in hyperglycemic serum and have served as a morphologic marker of teratogenesis.^{7,8}

This study was designed to determine if hyperglycemia would (1) result in decreased mitochondrial numbers or (2) modify mitochondrial morphologic development.

Material and methods

The explanted rat embryo model as developed by New⁶ and further described by Sadler⁸ serves as the basis of the present study. This model and all procedures and handling were approved by the Institutional Animal Care and Use Committee of the University of Kansas Medical Center.

Sprague-Dawley rats were maintained on a 12-hour-light/12-hour-dark cycle and provided with food and water at will. Vaginal smears were examined for sperm the morning after overnight mating. When intravaginal sperm was found, day 0 of the pregnancy was defined as the preceding midnight. Pregnant females were housed separately with food at will in 12-hour-light/12-hour-dark cycles.

Serum for culture media was prepared by cardiac puncture and exsanguination of Sprague-Dawley retired male breeder rats that were under halothane anesthesia. The blood was immediately centrifuged, and the serum was separated and immediately heat inactivated at 56° C for 30 minutes. Euglycemic serum was thus defined with a normal serum glucose level of approximately 125 mg/dl. Hyperglycemic serum was prepared by adding an additional 2.5 mg of D-glucose to each milliliter of the previously prepared euglycemic serum, for a final glucose concentration of approximately 400 mg/dl. Before the embryos were explanted, the serum was pregassed with 95% oxygen and 5% carbon dioxide and warmed to 38° C. Paired hyperglycemic and euglycemic serum was defined as that prepared from the same retired male breeder.

Pregnant females at days 10 to 11 were placed under halothane anesthesia, a laparotomy was performed, and the pregnant uterine horns were extirpated and transferred to a sterile culture dish containing physiologic saline solution at 38° C. Adjacent embryos were dissected free by opening the anterior wall of the uterus under direct vision with a dissecting microscope. Reichert's membrane, with the attached trophoblast and parietal ectoderm, was removed and opened. The visceral

yolk sac, amnion, and ectoplacental cone were left intact and explanted with the embryo. The paired embryos were then transferred to paired hyperglycemic and euglycemic sera. Each embryo was cultured in 3 ml of serum in a pregassed, closed flask (volume 10 ml) for 4 hours in an incubator at 38° C. At the end of 4 hours, the serum was replaced with pregassed, paired hyperglycemic and euglycemia sera (as previously determined) and the culture continued at 38° C for an additional 4 hours. Four embryos were explanted from one dam (dam F) with one embryo cultured in hyperglycemic sera for 8 hours and one in euglycemia sera for 8 hours as described. The other two embryos were cultured in alternating sera with one embryo cultured in hyperglycemic serum for 4 hours, then in euglycemia serum for the final 4 hours, and the other embryo cultured in euglycemic serum for 4 hours, followed by hyperglycemic serum the final 4 hours.

At the conclusion of the 8-hour culture interval, the paired embryos were viewed under the dissecting microscope. Only those pairs for which adequate embryonic heart activity was demonstrated (heart rate >100 beats/min) were prepared for cellular studies.

Crown-rump lengths were obtained at the end of the 8-hour incubation. Embryos were then immediately fixed in Karnovsky's fixative for 4 hours, followed by 2% glutaraldehyde for 48 hours. Embryos were then placed in 1% osmic acid for 1 hour. Serial alcohol dehydration was performed and the embryos then embedded in resin (L.R. White, Ted Pella, Inc.). Thick sections were stained with toluidine blue and blocks trimmed for electron microscopic studies. Cells of the anterior neuropore were examined with the transmission electron microscope. For each embryo of the paired embryo cultures, serial sections in the region of the anterior neuropore were performed. Transmission electron micrographs were obtained at magnifications of ×8120 to ×28,000.

Mitochondria were classified as to morphologic type (type I or type II) in accordance with described criteria on the basis of shape, matrix density, and cristae width. ¹⁵ Specifically, type I mitochondria have an elongated longitudinal cross section, a dark matrix density, and an average cristae width of 80 nm. Type II mitochondria are circular in cross section, have a light matrix, and have a mean cristae width of 45 nm. The types of ≥60 mitochondria in the region of the anterior neuropore were identified for each embryo (range 60 to 164).

The transmission electron micrographs were transferred to a MacIntosh computer (Apple Computers) by means of a Hewlett-Packard Laserscanner and graphic software. Cytoplasmic, nuclear, and mitochondrial areas were determined by graphic software for a minimum of 7 cells in the region of the anterior neu-

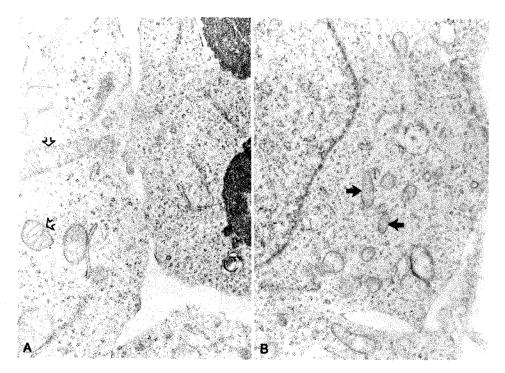

Fig. 1. Transmission electron micrographs of embryonic cells in region of anterior neuropore of paired rat embryos explanted at 10 days and cultured for 8 hours. A, Euglycemic serum as culture media for 8 hours with open arrow demonstrating typical type II mitochondrial morphologic characteristics. B, Hyperglycemic serum as culture media for 8 hours with closed arrow demonstrating typical type I mitochondrial morphologic characteristics. (Original magnification ×28,000.)

ropore for each embryo (range 7 to 12 cells). The number of mitochondria observed in each cell was recorded. The average mitochondrial area, the average number of mitochondria per cytoplasmic area, and the ratio of the mitochondrial area to cytoplasmic area for each embryo were then determined. During the computer analysis, the examiner was blinded as to whether the embryo had been cultured in euglycemic, hyperglycemic, or alternating sera.

Statistical studies were performed for the paired embryos cultured in the euglycemic and hyperglycemic serum. Nonparametric statistical analyses were used for the comparison of the morphologic types of mitochondria (percentages). The number of mitochondria per cytoplasmic area, average mitochondrial area, and mitochondrial area/cytoplasmic area ratios were compared by the paired t test. Statistical significance was defined as p < 0.05.

Results

Successful cultures were completed in four of five paired studies with two embryos from each of dams A through E and in four of four embryos cultured from dam F. For one pair of embryos no cardiac motion was noted for the embryo cultured in hyperglycemic sera. Therefore the overall rate of culture success was 92%

(11 of 12 explanted embryos). No morphologic anomalies were visualized at the conclusion of the 8-hour culture interval.

A significant difference in embryonic growth was demonstrated for paired embryos cultured in hyperglycemic sera versus euglycemic sera, with an average decrease in final crown-rump length of 10.5%. Paired t test demonstrated a significance of p < 0.02 for the final crown-rump lengths of the paired embryos.

Fig. 1 demonstrates comparison of mitochondria typically seen in embryos cultured in euglycemic and hyperglycemic serum. No difference in the number of mitochondrial per cytoplasmic area (mitochondrial density) was demonstrated between those embryos grown in euglycemic sera and the paired embryos cultured in hyperglycemic sera (Table I, p = 0.59).

The average mitochondrial area (paired t test, p = 0.004) and the ratio of mitochondrial area to cytoplasmic area (paired t test, p = 0.04) were determined to be decreased for those embryos cultured in hyperglycemic sera as compared with the paired embryos cultured in euglycemic sera (Table I).

The percentage of mitochondria in the condensed form (type I) as compared with the orthodox configuration (type II) was increased for those embryos cultured in hyperglycemic sera versus the paired embryos

Table I. Comparison of mitochondrial parameters and crown-rump lengths for paired embryos cultured in hyperglycemic and euglycemic media

	Type of culture media			
	Hyperglycemic	Euglycemic	Statistics	
Crown-rump length (mm)	3.48 ± 1.06	3.88 ± 1.1	p < 0.02 (paired t test)	
Mitochondria per cytoplasmic area (No./ μm^2)	0.042 ± 0.230	0.036 ± 0.018	p = 0.59 (paired t test)	
Average mitochondrial area (µm²)	0.023 ± 0.011	0.051 ± 0.021	p = 0.004 (paired t test)	
Mitochondrial/cytoplasmic area ratio	0.038 ± 0.013	0.072 ± 0.014	p = 0.04 (paired t test)	
Mitochondria in type I configuration (%)	78.8 ± 12.6	20.4 ± 6.9	p = 0.03 (Wilcoxon signed-rank)	

Table II. Effects of alteration of glucose environment on mitochondrial morphologic for embryos of dam F

	Constant euglycemia	Constant hyperglycemia	Hyperglycemic for 4 hr then euglycemic for 4 hr	Euglycemic for 4 hr then hyperglycemic for 4 hr

cultured in euglycemic sera (Table I, Wilcoxon signed-rank test, p < 0.02).

Reversed cultures in the embryos cultured from dam F demonstrate the mitochondrial studies to be dependent on the type of sera used in the final 4 hours of the culture. Mitochondrial morphologic type and dimensions reversed within 4 hours, as demonstrated in Table II. In addition, the final crown-rump lengths were decreased for those embryos exposed to hyperglycemia, with the most significant decrease experienced by the embryo initially cultured in hyperglycemia then suddenly changed to euglycemic media (Table II).

Comment

Congenital malformations are the major cause of the increased perinatal mortality experienced by the offspring of insulin-dependent diabetic mothers. Hyperglycemia remains the factor most often cited as being involved in the teratogenic process; however, the exact mechanism has yet to be elucidated. The Crabtree effect (reversed Pasteur effect) occurs when a cell exposed to hyperglycemia experiences a decrease in aerobic metabolism and a switch to the glycolytic pathways. Reid⁹ hypothesized that a cell so exposed would experience a decrease in mitochondrial biogenesis. Should this cell suddenly be removed to an environment with a lower glucose concentration, the cell would experience a time interval during which energy production capability would be reduced until such time as

appropriate mitochondrial numbers could be regenerated. This time interval Reid defined as the *energy gap*. For a developing embryo, such a gap could be expected to result in cells incapable of meeting temporal and spatial requirements, thereby producing structural defects. To date, this hypothesis has not been studied in mammalian embryos.

Our data do not, however, support the decrease in number of mitochondria in rat embryos exposed to hyperglycemia, as would be expected by Reid's original hypothesis. Rather, no statistical difference in the number of mitochondria per cytoplasmic area (mitochondrial density) existed in those paired embryos cultured in hyperglycemic versus euglycemic sera. The data do, however, demonstrate a marked difference in mitochondrial morphologic features as evidenced by mitochondrial size and morphologic subtype.

Alterations in mitochondrial morphologic subtype have been clearly demonstrated to indicate alterations in the metabolic activity of the mitochondria. Type II mitochondria are indicative of an energized cell and are induced with the addition of intracellular adenosine triphosphate. Predominantly type I mitochondrial configurational changes are induced by the addition of intracellular adenosine diphosphate and are thus indicative of a lower energy state. Indeed, the appearance of type I mitochondria requires a phosphate acceptor, e.g., adenosine diphosphate, in addition to a substrate. Our data thus provide evidence for alteration

in cellular metabolic activities in cells of the developing rat embryo exposed to hyperglycemia, an alteration that is further demonstrated to be reversible in matched embryos.

Hyperglycemia certainly could result in alterations of mitochondrial morphologic features by other mechanisms or other messengers. For example, recent studies by Horton and Sadler¹⁹ described an alteration in mitochondrial morphologic type of explanted rate embryos exposed to β-hydroxybutyrate. Specifically, a decrease in type I mitochondria was demonstrated in those cells exposed to this ketone. Ketones are metabolized within the mitochondria; therefore it is speculated that this substrate may serve to activate the mitochondria and increase metabolic activity.20

Sadler and Hunter²¹ and Akazawa et al.²² have demonstrated that exposure to hypoglycemia also can be teratogenic. The latter study demonstrates that sudden alterations in glucose concentrations can have profound effects on the teratogenic process. For those explanted embryos cultured in euglycemia sera for 48 hours, the incidence of malformations was 0%. Embryos were then cultured in euglycemic sera for 8 hours, exposed to hypoglycemic sera for 1 hour, and then cultured in euglycemic sera for the final 39 hours. The incidence of major malformations was 7.1%. When the experiment was performed with 33.3 mmol/L glucose sera rather than euglycemia media, the incidences of major malformations was 0% and 21.2%, respectively, for those embryos not exposed and exposed to brief hypoglycemia. These results were abolished when glucose was added to the hypoglycemic sera. Furthermore, the addition of insulin to the nonhypoglycemic sera did not produce major malformations.

These findings by Akazawa et al.22 are of major significance in that they demonstrate that sudden substrate changes are more teratogenic than constant exposure to hyperglycemia. That a significant incidence of malformations could be induced at a glucose level previously found not to be teratogenic in a constant culture environment argues against hypotheses centering on elevated metabolic byproducts of glucose (e.g., sorbitol) as the primary process of diabetic teratologic development. However, altered cellular energy production capabilities could provide such an explanation.

Another possible mechanism is altered phospholipid metabolism and biogenesis, such as the hypothesis described by Naftolin et al.28 for the developing embryo and yolk sac. They speculate that alteration of the yolk sac membrane results in embryonic asphyxia. Abnormalities in the yolk sac membrane also are supported by Sussman and Matschinsky.24 Arachidonic acid25 and myoinositol²⁶ supplements are known to abolish the teratogenic effects of hyperglycemia. Because mitochondria are the site of conversion of pyruvate to acetyl coenzyme A (the major fatty acid precursor) and the site of fatty acid metabolism, altered mitochondrial function would be expected to result in altered lipid metabolism.

Further evidence for the potentially increased teratogenesis of sudden alterations in glucose levels is provided by the decreased crown-rump lengths for embryo from dam F, which was cultured in hyperglycemia followed by euglycemia. The strong correlation between growth abnormalities and malformations for embryos subjected to a diabetic environment has been well established both in vivo^{7, 8, 25} and in vitro.²⁷ The most profound decrease in embryonic growth was for the embryo initially cultured in hyperglycemia then suddenly switched to a euglycemic environment. This is as predicted should sudden alterations in glucose milieu be a mechanism of diabetic teratogenesis.

We therefore suggest that the Reid hypothesis be modified to describe a metabolic gap to result from a modification of the mitochondrial metabolic capacity (as evidenced by mitochondrial morphologic characteristics) rather than a decrease in the number of mitochondria or mitochondrial density. A swing from a hyperglycemic environment to a euglycemic environment would still result in either (1) a decreased energy production capacity adequate to meet spatiotemporal demands or (2) decreased phospholipid production with profound effects on cellular membranes, cellular communication, and calcium channels of the developing embryo. This effect(s) would continue until such time as the mitochondria had altered to a more active or appropriate metabolic morphology. The demonstration of the reversibility of mitochondrial morphology adds further support for this hypothesis.

Current studies continue to demonstrate the effect of episodic hyperglycemia on embryonic growth and development as compared with constant hyperglycemia. Further studies of precise biochemical markers for intracellular metabolic pathways, including fatty acid metabolism and glucose metabolism, are in progress.

The potential for embryonic damage by sudden metabolic swings has been suggested by several investigators.21, 23, 24 Demonstration of support for the modified Reid hypothesis would have important implications in the care and management of the insulin-dependent diabetic woman in the first trimester of pregnancy, i.e., insulin schedules and dosages structured to avoid rapid altertaions of levels of maternal glucose.

Demulen[®]1/35

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

Where protection begins

The physician should become familiar with the prescribing information (labeling) for this product, which discusses reported risks, such as thromboembolic disorders (including strokes and heart attacks), risk of estrogen dose, and hepatic lesions, as well as the need to monitor patients for early symptoms of any diseases or medical conditions, so use can be discontinued when appropriate.

Please see adjoining page for a brief summary of prescribing information.

The OC innovator **SEARLE**

DEMULEN® 1/35 Where protection begins (ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

BRIEF SUMMARY

Demulen® 1/35: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 35 mcg. Each blue tablet in Demulen 1/35:28 is a placebo containing inert Ingredients. Demulen® 1/50: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 50 mcg. Each pink tablet in Demulen 1/50:28 is a placebo containing inert Ingredients. Indication and usage: For prevention of pregnancy. Pregnancy are for products with ≥ 35 mcg ethinyl estradiol or ≥ 50 mcg mestranol is ≤1/100 woman-years. With ≤35 mcg ethinyl estradiol, rate is slightly higher, with progestogen-only oral contraceptives (OC3), rate is about 3. Precise comparisons cannot be made. Rates for other methods have been published. Dose-related Thromboembolic Risk. Studies showed positive association between OC estrogen dose and thromboembolic risk. It is in keeping with good therapsutics to minimize estrogen exposure. Prescribe product containing least amount of estrogen compatible with acceptable prepancy rate and patient acceptance. Start new users on ≤50 mcg estrogen. Contraldifeations: Thromboembolic disorders, past history of deep vien thromboembolic bis or thromboembolic disorders carebrovascular disease, myocardial infarction or coronary atery disease, or past history of these: known or suspected breast carcinoma, estrogen-dependent neoplasia, or pregnancy: undiagnosed abnormal genital bleeding; past or present, benign or malignant liver tumors developing during use of estrogenic products.

Cigarette-smoking increases risk of serious cardiovascular side effects from OC use. Risk increases with age and heavy smoking (15 or more cigarettes/day) and is quite marked in women over 35. OC users should be strongly advised not to smoke. OCs are associated with increased risk of several serious conditions including venous and arterial thromboembolism, thrombotic and hemorrhagic stroke, myocardial infarction, visual disorders, hepatic tumors, gallbladder disease, hypertension, fetal abnormalities. Practitioners should be familiar with the available information relating to disease, hypertension these and other risks.

disease, hypertension, tetal adnormalines. Practitioners should be ramiliar with the available information relating to these and other risks.

1. Thromboembolic disorders and other vascular problems: increased risk of thromboembolic and thromboembolism (TE). British and U.S. studies showed increased risk for nonfatal disease. U.S. studies showed increased risk for stroke. OC users were 2-11 times more likely to manifest these diseases without evident cause. In a study of Idiopathic deep vein thromboels and pulmonary embolism (PE), projected hospitalization rates for ages 16-40 were 47/year/100,000 users and 5 for nonsers. Overall excess mortality from PE or stroke was 1.3-3.4 detaths/year/100,000 users and increased with age referbrovascular disorders: In a study of stroke with and without predispositions, risk of hemorrhagic stroke was 2 times greater and thrombotic stoke 4.0-9.5 times greater in users. Mortality trends in 21 countries indicate that changes in cardiovascular mortality were associated with changes in OC prevalence. The Royal College of GPs (RCGP) reported on its prospective study: "A statistically significant higher rate of reporting of cerebrovascular accidents in Itakers is evident, but the numbers are too small to lipsify an estimation of the degree of risk." A 1981 analysis showed a 4-fold increased mortality in users from circulatory diseases, mainly myocardial infarction (Mi) and hemorrhagic stroke. Excess mortality was associated with age and smoking, A. 1983 analysis showed a 4-fold increased mortality in users from circulatory diseases, mainly myocardial infarction (Mi) and hemorrhagic stroke. Excess mortality was associated with smoking, age, and Mi were increased. Women over 30 had more arterial disease, being greatest in smokers. Arterial case-fatality was 2-3 times greater for venous thrombosis and PE was 4-fold and statistically significant. Mortality from nontheumatic heart disease was greater in ever-users. In the Walant Creek Study, subarachnolib hemorrhage risk was associated

Estimat	ed Mortality Rate	from Myc	ocardial Infarction	per 100,000 Women	Year

**Nisk of Dose: Reports of TE after use of OCs with ≥50 mcg estrogen received by drug safety committees in Britain, Sweden, and Denmark were compared with distribution expected from market research sales estimates. A positive correlation was found between estrogen dose and reporting of TE, including coronary thrombosis, in excess of that predicted by sales. OCs with ≥100 mcg estrogen were associated with higher TE risk than those with 50-80 mcg. Estrogen quantity may not be the sole factor; influence of progestogens was not considered, which may be responsible for certain discrepancies in the data. No significant differences were noted between OCs containing same estrogen dose not between entityel estratiol and mestranol. In Britain certain TE conditions were associated with progestogen or estrogen dose. In Sweden reports of TE decreased when higher estragen doses were not longer prescribed. Studies on TE risk with progestogen-only OCs have not ben done. Cases have been reported for thase; they are not presumed free of risk. In a U.S. case-controlled study, relative risk of OC use 1 month before hospitalization for various types of TE was calculated. If relative estrogenic potency and possible influence of different progestogens are ignored. OCs may be divided into those with <000 mcg and those with ≥100 mcg estrogen. For all cases combined, larger doses were associated with only slightly higher risk, for idiopathic cases risk was doubled with larger doses, but confidence limits overlapped and differences were not significant. Apparently there was less increased risk for cases with predispositions. In FPA study no nonhemorrhagic strokes occurred with <50 mcg estrogen, vs 13 with higher doses. Later group also had more venous TE. TE risk in users and nonusers increases with age. OCs have been considered an independent risk factor. Decreased HDL, which relates to increased myccardial ischemia, occurs with high progestational activity Consider amount of both steroids in choosing OC.

Risk is: A-very high; B-high; C-moderate; D-low.	Age:	<30	30-39	≥40
Heavy smokers (≥ 15/day)		C	В	A
Light smokers (<15/day)		D	С	В
Nonsmokers, no predispositions		D	C,D	С
Nonsmokers, with predispositions		C	C.B	B.A

Re alert to earliest manifestations of TE disorders (eg. thrombophlebilis, PE, cerebroascular insufficiency, comparay artery disease, MI, retinal thrombosis, mesenteric thrombosis). Should any be suspected, discontinue OCs immediately. A 4-7-fold increased risk of postsurgery TE was reported in users; if feasible discontinue OCs at least 4 weeks before surgery or in prolonged immobilization. Before resuming OCs, welgn isks of postsurgery TE complications against contraceptive needs. RCOP reported higher incidence of superficial and deep vein thrombosis in users, the former correlated with progestogen dose. Varicose veins have little effect on development of deep vein thrombosis, 2. Deutar lesions; Neuro-ocular lesions such as optic neurities or retinal thrombosis have been associated with OCs. Discontinue if there is unexplained, gradual or sudden, partial or complete foss of vision; proptosis or diptopia; papilledema; or evidence of retinal vascular lesions. Institute diagnostic and therapeutic measures. 3. Carcinoma: Long-term estrogen in certain animals increases carcinomas and replasms, such as those of breast, ulerus, cervix, vagina, ovary, liver, pituitary. Some synthetic progestogens, none currently in OCs, increase incidence of benipn and malignant mammary nodules in dogs. Estrogens increase risk of human endometrial carcinoma. In case-controlled studies, increased risk (2.2-13.9 times) associated endometrial carcinoma with prolonged estrogen for menopausal symptoms. Risk was independent of other known risk factors and depended on duration of use and dose. This is supported by increased endometrial carcinomic incidence since 1968 in areas with cancer-reportions systems, which may be related to expanding estrogen use. There is no evidence that natural estrogens are more or less hazardous than synthetics. Of the first 30 cases of endometrial carcinoma in OC users under 40, those without predispositions occurred

nearly always with no-longer-marketed spauential OCs. No statistical association is reported suggesting increased enformet cancer with combination or progestiogen-enity OCs. Studies show no increased breast cancer with OCs or estrogens. Howe, greater risk was noted in OC users with beingin breast disease or long-term (2-4 years) use. One study found greater risk reast cancer with 2-4 years OCs or grint to list full-time programs, Pisk to breast cancer in connection with other reactors and in virtorio subjourps. Decrease in breign breast tumors in OC users is well known. Some studies suggest increased risk of cervical dysptasis, GN, encoion, and carcinoma in long-term users. Cervical microgranical hypotyplasis of the programs of the studies of increased cancer risk with OCs or extension and the studies of increased cancer risk with OCS or extension and the studies of increased cancer risk with OCS or extension and the studies of increased cancer risk with occare and take disponetic measures to rule out malignancy. Carchityl monitor users with strong family bistory of the causes and take disponetic measures to rule out malignancy. Carchityl monitor users with strong family bistory of the causes and take disponetic measures to rule out malignancy. Carchityl monitor users with strong family increased or with programs of cervical disposite 4. Hepatic adenomase, etc. have been associated with OCs, in 1 study OC formulations with high "hormunal potency" we associated with higher risk, as was an include the programmy of OC use when submitting specimens. Endocrine and liver function tests may be attered; repeat abnormal tests after stopp for 2 months. These have been observed: increased 65P retention and other abnormalities in liver function tests; increase prothorobin and coaguistion factors VII, VII, IX, X; decreased antiformobin ill, increased platelet against prothorobin and coaguistion factors VII, VIII, IX, X; decreased antiformobin ill, increased platelet against particular thyroid-binding globulin leading to increased circulating total thyroid homone (PBI, T*); decreased T* gutake, unaltered f* T*, decreased pregnanediol excretion; reduced metyrapone response; increased blood transcortin, corticosteroid, triglyceri phospholipid, reduced serum folate; impaired glucose tolerance; altered plasma trace minerals. Influence of protonged OC in on pituitary, ovarian, adrenal, hepatic, or uterine function, or on immune response not established. OCs my mask onset climacteric. Cervical chiamydial and gonorrheal prevalence is increased; do not assume OC protects against chiamydial P HIV sempositivity was associated with OC use. Information for patients. See patient liabeling. Oring interactions. Longitudinal changes in insulin release and insulin resistance in nonobese pregnant women

Patrick M. Catalano, MD,^{a,c} Elaine D. Tyzbir, MS,^a Noreen M. Roman, BS,^c Saeid B. Amini, PhD,^c and Ethan A.H. Sims, MD^b

Burlington, Vermont, and Cleveland, Ohio

To assess the longitudinal changes in insulin release and insulin sensitivity in nonobese normal women during gestation, six women were evaluated with oral glucose tolerance testing, body composition analysis, intravenous glucose tolerance tests, and the hyperinsulinemic-euglycemic clamp before conception, at 12 to 14 weeks, and at 34 to 36 weeks' gestation. There was a significant increase in the insulin/glucose ratio (p=0.028) during the oral glucose tolerance test during gestation. There was also a significant 3.0- to 3.5-fold increase throughout gestation in first-phase (p=0.001) and second-phase (p=0.0001) insulin release during the intravenous glucose tolerance test. Peripheral insulin sensitivity was estimated as the glucose infusion rate (in milligrams per kilogram fat-free mass per minute) during the hyperinsulinemic-euglycemic clamp. There was a significant (p=0.0003) 56% decrease in insulin sensitivity through 36 weeks' gestation. These results are the first to prospectively evaluate the longitudinal changes in maternal carbohydrate metabolism from the time before conception through late gestation with newer methods such as the hyperinsulinemic-euglycemic clamp. (Am J Obstet Gynecol 1991;165: 1667-72.)

Key words: Carbohydrate metabolism, insulin release, insulin sensitivity, pregnancy

Pregnancy has often been characterized as having a diabetogenic effect on normal carbohydrate metabolism, as manifested by hyperglycemia and hyperinsulinemia in response to maternal feeding. This combination of elevation in postprandial glucose and insulin response during gestation has been cited as the basis for decreased peripheral insulin sensitivity during pregnancy. The methods by which insulin sensitivity has been quantified during gestation have usually been equated with insulin response to a glucose challenge² or the rate of glucose disappearance during an intravenous glucose tolerance test (GTT). However, neither of these methods may adequately estimate peripheral insulin sensitivity.

Furthermore, the mechanism by which the anabolic changes in early pregnancy, such as increased maternal fat deposition, are mediated remain controversial. Various reports have described either increased,⁴ decreased,⁵ or unchanged⁶ insulin sensitivity or insulin

release⁷ in early pregnancy. These studies, however, relied on either postpartum evaluation⁷ or cross-sectional studies⁴ to estimate the changes in carbohydrate metabolism in early pregnancy.

The purpose of this prospective, longitudinal study

The purpose of this prospective, longitudinal study was to characterize the normative changes in insulin response and insulin sensitivity in healthy nonobese pregnant women. We chose to evaluate nonobese women as a distinct group from obese women, because of the potential affect of obesity on carbohydrate metabolism during gestation.⁸

Methods

Subjects. This study was performed in the General-Clinical Research Center at the Medical Center Hospital of Vermont from 1985 through 1989. The study was approved by the hospital's institutional review board, and informed consent was obtained from each subject before the study. Six healthy white women were recruited to participate. All had at least one previous uncomplicated term pregnancy. None had a family history of diabetes mellitus in a first- or second-degree relative or abnormal glucose tolerance in a previous pregnancy. None of the subjects were breast-feeding or using oral contraceptives, other medications, or tobacco. All were planning to conceive as soon as the baseline pregravid studies were completed.

Experimental protocol. The study design consisted of a series of experiments initiated before conception (five of six subjects during the follicular phase of the menstrual cycle) and repeated again during early (12)

to 14 weeks) and late (34 to 36 weeks) gestation. Each subject was instructed in a standard diet by the Clinical Research Center nutritionist 2 weeks before each study. The diet was designed to standardize nutritional intake for all subjects, maintain weight before conception, and apropriately increase weight during gestation.

All subjects were admitted to the General Clinical Research Center for a 3-day period of study. These studies were sequentially performed during the 3-day protocol: day 1, oral GTT; day 2, body composition analysis and intravenous GTT; day 3, the hyperinsulinemic-euglycemic clamp.

Oral GTT. Before conception all subjects were given a 75 gm oral GTT, as defined by the National Diabetes Data Group,⁹ and during pregnancy all subjects were given a 100 gm oral GTT. Normal glucose tolerance during gestation was defined by the criteria of Carpenter and Coustan.¹⁰ The changes in oral glucose tolerance over time were analyzed as the total area under the curve and the individual time points (fasting, and 1, 2, and 3 hours). The plasma glucose concentrations were determined by the glucose oxidase method with a Yellow Springs glucose analyzer. Insulin concentrations were measured by radioimmunoassay by the method of Starr and Rubenstein.¹¹

Intravenous GTT. For the intravenous GTT, we infused 0.5 gm/kg of glucose as a bolus over 3 minutes, and samples of glucose and insulin were obtained at 0, 1, 3, 5, 10, 15, 30, 45, and 60 minutes after the start of the infusion. The K value, or the rate of glucose disappearance from the circulation, was estimated according to the method of O'Sullivan et al. 12 The first-phase insulin response was estimated by measuring the area under the glucose curve from 0 to 5 minutes and the second phase, by measuring the area under the curve from 5 to 60 minutes.

Body composition analysis. Each subject's fat-free mass and body fat were estimated by underwater weighing with simultaneous correction for residual volume by helium dilution.¹⁸

Hyperinsulinemic-euglycemic clamp. The hyperinsulinemic-euglycemic clamp was performed as described by DeFronzo et al.¹⁴ to estimate insulin sensitivity. The hyperinsulinemic-euglycemic clamp involves a primed constant infusion of insulin, 40 mU/m² to

achieve a high level of insulin (approximately 100 $\mu U/ml).$ A variable infusion of 20% glucose was adjusted, on the basis of plasma glucose samples drawn every 5 minutes, to maintain plasma glucose at 90 mg/dl. The rate of glucose infusion during the last 40 minutes of a 2-hour infusion was then taken as the estimate of peripheral insulin sensitivity.

Statistical analysis. The data were expressed as the mean ± SD. Statistical analysis was performed by analysis of variance with repeated measures. The changes in early and late pregnancy were analyzed with a Dunnett test. Statistical analysis was performed with an SAS statistical package. Probability levels ≤0.05 were considered significant.

Results

The pregravid age, height, weight, body mass index, percent body fat and time between pregravid study and conception are shown in Table I. We defined nonobese subjects as those women having a pregravid percent body fat <25%.

Oral glucose tolerance. All subjects had normal oral glucose tolerance both before conception and during gestation. Since we used a greater (100 gm) oral glucose load during pregnancy than during the time before conception (75 gm), we estimated the changes in oral GTT results over time with the insulin/glucose ratio (Fig. 1). There was a significant increase (p = 0.028) in the area under the insulin/glucose ratio curve during gestation. The increase was significant in early (p = 0.04) but not late gestation. When the data were analyzed at each time point, there was a significant increase in the fasting (p = 0.03), 2-hour (p = 0.03), and 3-hour (p = 0.04) plasma insulin/glucose ratios during the course of study. These changes were significant for the fasting insulin/glucose ratio from early to late gestation (p = 0.05) and for the 2-hour insulin/glucose ratio from the time before conception through early gestation (p = 0.05).

Intravenous GTT. There was no significant change (p=0.72) in the rate of glucose disappearance or K value during pregnancy: pregravid, 1.84 ± 0.79 ; early pregnancy, 1.94 ± 0.62 ; and late pregnancy, 1.68 ± 0.39 . There was, however, a significant increase in the first- (p=0.001) and second-phase (p<0.0001) insulin response during the intravenous GTT (Figs. 2 and 3). These increases in first-phase insulin response were significant in both early (p=0.025) and late (p=0.025) gestation. The increase in second-phase insulin response was significant only in late gestation (p=0.001). The mean increases in insulin response by late pregnancy were 3.5-fold for first-phase insulin response and 3.0-fold for second-phase response, as compared with pregravid insulin responses.

Hyperinsulinemic-euglycemic clamp. There was a

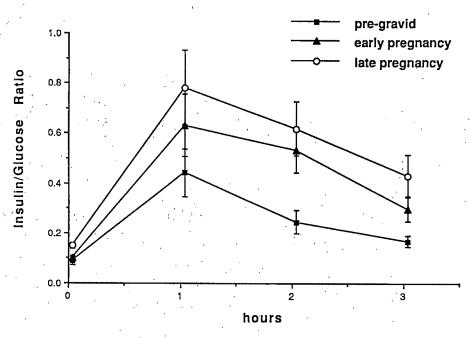

Fig. 1. Longitudinal changes in plasma insulin-glucose ratio during oral GTT (mean ± SD).

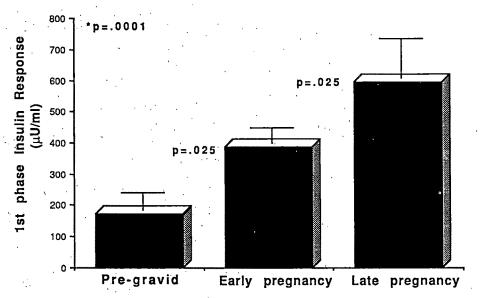

Fig. 2. Changes in first-phase insulin response during intravenous GTT (mean ± SD).

significant decrease (p = 0.0003) in the pregravid (10.5 ± 2.7) , early pregnancy (8.2 ± 2.5) , and late pregnancy (4.6 ± 1.3) glucose infusion rate (in milligrams per kilogram fat-free mass per minute), which represents a 56% decrease in insulin sensitivity from the time before conception through 34 to 36 weeks' gestation (Fig. 4). Thirty-nine percent of this decrease in insulin sensitivity occurred by 12 to 14 weeks' gestation (p = 0.04) and 61% of the decrease (p = 0.005) in insulin sensitivity by 34 to 36 weeks' gestation. These relationships remained essentially the same (pregravid, 8.7 ± 2.5 ; early pregnancy, 6.5 ± 2.0 ; and late preg-

nancy, 3.5 ± 1.0 ; p = 0.0001) when the glucose infusion rate was not corrected for fat-free mass in milligrams per kilogram per minute). Furthermore, there were no significant differences (p = 0.22) in the pregravid (97.6 \pm 18.7 μ U/ml), early (80.7 \pm 14.4 μ U/ml), or late (99.9 ± 27 μ U/ml) insulin concentration during the hyperinsulinemic-euglycemic clamp.

Comment

The findings are consistent with previous reports showing a progressive increase in insulin response to glucose during late gestation. Spellacy and Goetz² and December 1991 Am J Obstet Gynecol

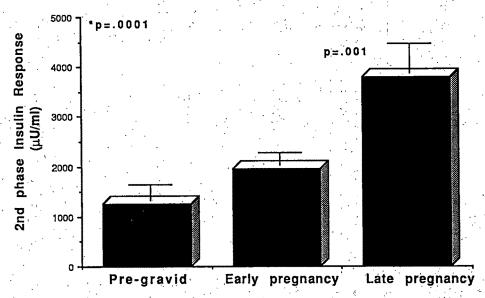

Fig. 3. Changes in second-phase insulin response during intravenous GTT (mean \pm SD).

Spellacy et al.15 showed a significant increase in insulin response to an intravenous GTT in mid to late pregnancy, when compared with the same subjects examined post partum. There was no significant difference, however, in insulin response at 13 to 15 weeks' gestation with the same study protocol. In contrast, our study examined baseline measurements before a planned pregnancy and showed a 120% increase in first-phase insulin response and a 50% increase in second-phase insulin response by 12 to 14 weeks gestation. The increases in late gestation were similar to those reported by Spellacy and Goetz.2 The reasons for the differences in results in early pregnancy remain unknown. We speculate that postpartum measures of insulin response may still be elevated postpartum in comparison with those obtained before conception.

The results of our study generally agree with previous reports showing a significant decrease in insulin sensitivity in late gestation. The studies of Fisher et al., 16 using a high-dose glucose infusion test, showed that normal pregnant women <85th percentile standard of body weight at 38 to 40 weeks' gestation had a decrease of about 80% in the insulin sensitivity index of that observed in a nonpregnant group. Buchanan et al.,17 with the minimal model technique, found that insulin sensitivity in normal pregnant women at 29 to 36 weeks' gestation was only one third of that of a group of normal nonpregnant women of a similar age and relative weight. Both these studies, however, used a crosssectional study design. Ryan et al.,18 as part of a study using the euglycemic clamp technique at 40 mU/m2/min, evaluated insulin sensitivity in nonpregnant women in comparison with a group of normal pregnant women, two of whom had repeat studies post

partum. They found that the pregnant women, in comparison with nonpregnant women, had glucose infusion rates that were decreased by 33% in late pregnancy. In the two pregnant women who were restudied 3 days postpartum, the glucose infusion rates returned to levels seen in the nonpregnant group. Of note, these studies were completed between 33 to 39 weeks' gestation, and the pregnant subjects' weight were a mean of 117% ideal body weight adjusted for pregnancy.

Our study differs from previous reports by the nature of the longitudinal study design and the method used to estimate insulin sensitivity. These experiments in healthy nonobese women on a standard diet allowed us to measure the changes in insulin sensitivity with minimal interference from factors other than pregnancy. The 56% decrease in insulin sensitivity by 34 to 36 weeks' gestation in normal pregnant women is comparable to the 66% decrease reported by Buchanan et al.17 and greater than the 33% reported by Ryan et al.18 but less than the 78% reported by Fisher et al.16 Whether these significant alterations in maternal metabolism during gestation have any permanent effects in these women remains to be examined. Our study did not address this question. We used only parous subjects in our protocol and did not evaluate these women post partum. A study using similar methods in nulligravid subjects before, during, and after their first pregnancy would be useful in answering this important question. For example, the available literature is contradictory regarding the importance of parity as a risk factor in the development of type II diabetes mellitus. 19, 20

All these estimates of insulin sensitivity in late pregnancy, however, are probably overestimates of true ma-

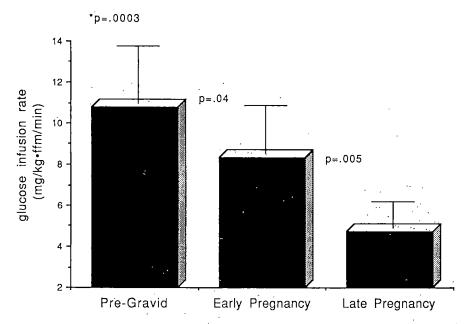

Fig. 4. Changes in glucose infusion rate during hyperinsulinemic-euglycemic clamp (mean ± SD).

ternal insulin sensitivity, because of the noninsulin-mediated glucose transport to the fetus by the placenta. Because of the limitations of our method, we were unable to distinguish the amount of the exogenous glucose infusion taken up by maternal tissues from that being transported to the fetus. Estimates of the partition of maternal glucose production between the conceptus and maternal tissues, however, has been examined by Hay et al.21 with the late-gestation pregnant ewe model. Approximately one third of maternal glucose utilization was accounted for by uterine glucose uptake (uterus, placenta, and fetus). Additional studies using this model by the same investigators have shown that fetal glucose use had a linear correlation (r = 0.89) with maternal arterial plasma glucose concentration.22 However, the maternal-to-fetal transport of glucose may be altered in certain situations. DiGiacomo and Hay23 have recently reported endogenous glucose production by the fetal lamb in late gestation during episodes of hypoglycemia and hypoinsulinemia. We anticipate that with the availability of cordocentesis, additional information regarding human maternal-fetal glucose metabolism will be forthcoming.

The available information on insulin sensitivity and carbohydrate metabolism in early pregnancy is controversial. Kalkhoff et al.4 believe that there is increased insulin sensitivity in early pregnancy, on the basis of improved intravenous GTTs in pregnant women during the first trimester relative to nongravid controls. Interestingly, the K values in our subjects also showed an increase, albeit nonsignificant, from 1.84 to 1.94 from the time before conception to 12 to 14 weeks' gestation. Coustan and Felig⁶ postulate that the decreased need for insulin in early gestation in insulindependent diabetic women is a function of decreased glucose availability. Knoop et al.24 ascribe enhanced maternal fat storage in early pregnancy to increased insulin secretion associated with increased caloric intake. The results of our study show that each of these women had evidence of decreased insulin sensitivity by 12 to 14 weeks' gestation; the mean decrease in the glucose infusion rate was 2.3 mg/kg fat-free mass per minute with a decrease in the range of 4.6 to 0.8 mg/kg fatfree mass per minute. We believe that the decrease in insulin sensitivity during gestation is associated with the increases in maternal body fat in early gestation that are necessary precursors for providing both fetal and maternal energy requirements in late gestation. A similar mechanism has been used to explain the early changes in the pathogenesis of type II diabetes in Pima Indians.25

The changes in insulin sensitivity during gestation in this study with the hyperinsulinemic-euglycemic clamp are not equivalent to estimates with the insulin/glucose ratio with the oral GTT or K value with the intravenous GTT. There was little or no significant change in either of these estimates of insulin sensitivity during gestation in our study subjects. This, however, may represent β error because of the relatively small number of subjects examined. Furthermore, we recognize that the methods we used estimate only peripheral insulin sensitivity. For the purposes of this report, we have assumed, as have others, that the elevated insulin concentrations during the hyperinsulinemic-euglycemic clamp suppress hepatic glucose production in these healthy normal subjects14 and that the glucose infusion rate was equated with peripheral insulin sensitivity. We are in the process of examining whether this assumption is correct by analyzing whether infused 6-6 dideuterated glucose during the hyperinsulinemic-euglycemic clamp showed complete suppression of hepatic glucose production

In summary, we report the first application of the hyperinsulinemic-euglycemic clamp in estimating the longitudinal changes in peripheral insulin sensitivity in pregnant women. We found that in nonobese normal women there is a significant 56% decrease in insulin sensitivity through 34 to 36 weeks' gestation. Of note, 39% of the total decrease in insulin sensitivity was evident by 12 to 14 weeks' gestation. Accordingly, this decrease in insulin sensitivity was associated with a 3.0-to 3.5-fold increase in insulin release by 34 to 36 weeks' gestation.

We thank the nursing staff of the Clinical Research Center for their assistance, Dr. David Robbins and Patricia Mead, MS, for performing the insulin assays, and Elizabeth Hiser, RD, John Hiser, MS, and Catherine Armstrong, BS, for their expert technical assistance.

Streptozocin-induced diabetes mellitus in the pregnant ewe

Jan E. Dickinson, MD, Bruce A. Meyer, MD, Susie Chmielowiec, MS, and Sue M. Palmer, MD

Houston, Texas

To evaluate the effects of streptozocin on maternal pancreatic β-cell function, we administered the agent to 14 pregnant ewes at 85 to 90 days' gestation on two occasions, 4 days apart. Intravenous glucose tolerance tests were performed before the initial administration, before the second dose, and 4 weeks after the final dose of streptozocin. There was a significant elevation in maternal fasting blood glucose (82 \pm 8.1 mg/dl before streptozocin and 102.6 \pm 6.8 mg/dl after streptozocin, ρ < 0.05). Five late-gestation ewes were used as controls, and a significant elevation in fasting plasma glucose levels was found in the streptozocin-treated animals (71.4 \pm 7.1 mg/dl control vs 102.6 \pm 6.8 mg/dl after streptozocin, p < 0.05). The glucose tolerance test curves showed a significant elevation 4 weeks after streptozocin compared with before streptozocin (p < 0.05). The maternal insulin response to streptozocin demonstrated a loss of the second-phase insulin response to the glucose load after one dose of streptozocin and loss of the first phase after two doses. The fetuses of the streptozocin-treated ewes showed a significant elevation in plasma glucose level compared with that of controls (13.3 ± 0.8 mg/dl, n=5) vs 42.1 \pm 8.1 mg/dl, n=10; p<0.05, control vs streptozocin, respectively). There was a consistent trend to fetal hyperinsulinemia in the fetuses of the streptozocin-treated ewes, although this did not achieve statistical significance (3.3 \pm 0.8 μ IU/ml, n = 5 vs 9.6 \pm 2.5 μ IU/ml, n = 10; p = 0.06, control vs streptozocin, respectively). The fetal insulin/glucose ratio was preserved in the streptozocin-treated ewes. Comparison of fetal weights between the control and diabetic ewes showed a significant increase in fetal weight in the fetuses of diabetic ewes (3280 ± 46 gm in control fetuses vs 3710 \pm 54 gm in diabetic fetuses, p < 0.05). The alterations in the maternal glucose and insulin response resulting from streptozocin-induced pancreatic β-cell destruction combined with elevations in fetal glucose, insulin, and weight provides a large animal model suitable for investigation of gestational diabetes in pregnancy. (AM J OBSTET GYNECOL 1991;165:1673-7.)

Key words: Diabetes, pregnancy, ovine, streptozocin

Maternal diabetes mellitus continues to contribute significantly to perinatal mortality and morbidity. Basic science investigations of diabetes mellitus have been limited by the lack of appropriate large-animal models. Diabetes mellitus has been successfully induced in smaller animals, but these studies have been hampered by the inability to repeatedly sample the fetus.

Streptozocin, a naturally occurring nitrosourea, has been shown to induce diabetes in small research laboratory animals such as the rat, dog, and rhesus monkey.¹⁻³ Previous work by S.M.P. produced varying degrees of maternal hyperglycemia, resulting in a heterogeneous population representing a diversity of clinical states. Experimentation with different dosage

regimens has refined the model to produce a more homogeneous animal preparation with consistent, modest glucose elevations and preservation of maternal health. In this article we are characterizing the maternal and fetal carbohydrate changes in this homogeneous animal model.

Material and methods

Fourteen pregnant Western-bred ewes of known gestational age received intravenous streptozocin (The Upjohn Co., Kalamazoo) on two separate occasions, 4 days apart, commencing at 85 to 95 days' gestation. Before each injection of streptozocin, a 3-hour intravenous glucose tolerance test with 25 gm of glucose administered as 50 ml of 50% dextrose in water was conducted. At the completion of the glucose tolerance test, streptozocin was administered to the ewe at a dose of 50 mg/kg maternal weight. Immediately before injection, the streptozocin was reconstituted in 50 ml of sterile 0.9% sodium chloride and then infused over 3 to 4 minutes via a peripheral hind limb vein. To ensure active secretion of insulin and maximal degranulation of the pancreatic β-cells, the streptozocin was injected while the animals were feeding. A third maternal in-

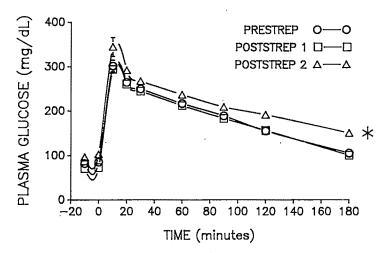

Fig. 1. Maternal glucose tolerance test profiles before streptozocin (*Pre-strep*)), after one dose of streptozocin (*Post-strep* 1), and 4 weeks after two doses of streptozocin (*Post-strep* 2) (n = 14). Data are mean \pm SEM. Asterisk, p < 0.05.

travenous glucose tolerance test was performed at 115 to 120 days' gestation.

To control for possible alterations in glucose tolerance with advancing gestation, five pregnant ewes of the same breed and supply source underwent intravenous glucose tolerance testing at 117 to 122 days' gestation.

Maternal and fetal vascular catheters were inserted with the animals under general anesthesia at 120 to 127 days' gestation, and the animals were used for other planned experimentation as approved by the University of Texas Medical School at Houston Animal Welfare Committee. Fetal plasma was sampled in both control and streptozocin-treated animals 5 to 7 days after surgery, before other planned experimentation. All experiments were conducted with the ewes standing in metabolic cages with free access to food and water. Four fetuses of streptozocin-treated ewes did not survive the perioperative period. The postoperative fetal loss rate in the streptozocin-treated ewe appears greater than that of the euglycemic ewe, an observation we attribute to the effects of maternal hyperglycemia on fetal catecholamine levels and the reduced ability of these fetuses to cope with stress (unpublished observations).

Maternal and fetal plasma glucose levels were assessed with a glucose analyzer (model 23A, Yellow Springs Instrument Co., Yellow Springs, Ohio). Maternal and fetal plasma insulin levels were measured by specific insulin radioimmunoassay (ICN Micromedic systems, Horsham, Pa.).

After the animals were killed at the completion of experimentation, weights for the fetuses of the streptozocin-treated ewes and control ewes were compared. Statistical analysis was performed by independent

Student t test and two-way analysis of variance with a computer statistical software package (Abstat, Anderson-Bell, Parker, Colo.). All data are mean \pm SE. A probability of p < 0.05 was chosen to represent statistical significance.

Results

After streptozocin administration, the fasting venous plasma glucose values rose significantly from a pretreatment level of 82.0 ± 8.05 to 102.6 ± 6.85 mg/dl 4 weeks later, p < 0.05. The glucose tolerance curves for the streptozocin-treated ewes are shown in Fig. 1. There was a significant increase in maternal plasma glucose level from baseline at all sampling intervals 4 weeks after streptozocin. Glucose values at 1 hour increased from 215 ± 7.9 mg/dl before streptozocin to 240 ± 8.0 mg/dl 4 weeks later (p < 0.05), values at 2 hours rose from 154 ± 9.1 to 191 ± 9.2 mg/dl (p < 0.05) and values at 3 hours rose from 105 ± 9.0 to 150 ± 8.5 mg/dl (p < 0.05).

The fasting plasma glucose levels of the control ewes (117 to 122 days' gestation) were significantly lower when compared with those of the gestation-matched streptozocin-treated ewes (71.4 \pm 7.1 vs 102.6 \pm 6.85 mg/dl, respectively, p < 0.05).

The serial maternal insulin responses to streptozocin are shown in Fig. 2. The maternal fasting insulin levels decreased from $22.6 \pm 2.76 \, \mu \text{IU/ml}$ before streptozocin to $12.6 \pm 2.70 \, \mu \text{IU/ml}$ 4 weeks after the second dose of the agent (p < 0.05). Within 4 days of the initial streptozocin administration there was a significant attenuation of the phase 2 insulin response, with preservation of the phase 1 response. Assessment at 4 weeks after the second dose of streptozocin revealed loss of

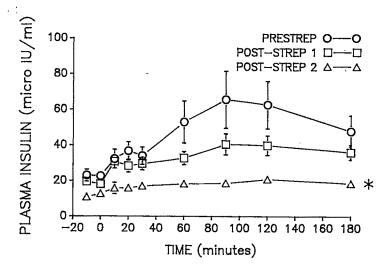

Fig. 2. Maternal insulin responses to intravenous glucose tolerance testing before streptozocin (Prestrep), after one dose of streptozocin (Post-strep 1), and 4 weeks after two doses of streptozocin (Poststrep 2) (n = 14). Data are mean \pm SEM. Asterisk, p < 0.05.

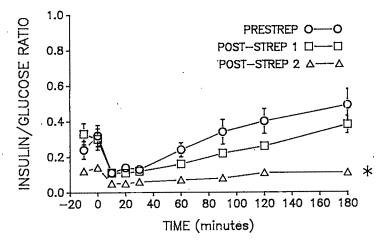

Fig. 3. Maternal insulin/glucose ratios in response to intravenous glucose tolerance testing before streptozocin (Pre-strep), after one dose of streptozocin (Post-strep 1), and 4 weeks after two doses of streptozocin (Post-strep 2) (n = 14). Data are mean \pm SEM. Asterisk, p < 0.05.

the phase 1 response and a picture of profound maternal insulinopenia with lack of insulin response to glucose challenge.

As the absolute insulin levels vary between individuals and plasma insulin concentrations should be interpreted in the context of the simultaneous glucose values, we examined the insulin/glucose ratio, a more sensitive index of pancreatic function.4 The maternal insulin/glucose ratios at the three sampling intervals are demonstrated in Fig. 3. The baseline fasting insulin/glucose ratio of 0.32 in the streptozocin-treated group was significantly reduced to 0.12 4 weeks after the second dose. The insulin/glucose ratio values were attenuated at each sampling interval throughout the glucose challenge after streptozocin.

The fetal glucose and insulin response after maternal administration of streptozocin is displayed in Fig. 4. The fetal plasma glucose levels of the streptozocintreated ewes were $42.1 \pm 8.1 \text{ mg/dl}$ (n = 10), which were significantly elevated when compared with the control fetal plasma glucose values of 13.2 ± 0.8 mg/dl (n = 5), $p \le 0.05$. The fetal plasma insulin levels of the streptozocin-treated ewes were consistently higher than those of the control fetuses, although not quite achieving statistical significance (9.62 ± 2.5 $\mu IU/ml$, $n = 10 \text{ vs } 3.3 \pm 0.8 \,\mu IU/ml$, n = 5; p = 0.06, streptozocin-treated vs control, respectively). The insulin/glucose ratio of the fetus of the diabetic ewe was 0.23, which did not differ from that of the five control fetuses, 0.25 (p > 0.05).

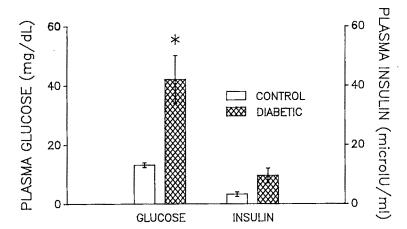

Fig. 4. Fetal plasma glucose and insulin values for streptozocin-treated ewes (n = 10) and control ewes (n = 5). Data are mean \pm SEM. Asterisk, p < 0.05.

Comparison of fetal weights between the euglycemic controls and the streptozocin-treated ewes revealed a significant increase in fetal weight at equivalent gestations in the streptozocin-treated group (3280 \pm 46 vs 3710 ± 54 gm, control vs streptozocin, p < 0.05).

Comment

The diabetogenic effect of streptozocin was first reported in 1963 by Rakieten et al. This agent has been used therapeutically in man to treat metastatic pancreatic islet cell carcinoma and in small laboratory animals to induce diabetes for research purposes. In these animal experiments, streptozocin induced a diabetic state similar to human hyperglycemia nonketotic diabetes. This effect appears to be mediated via reduction of β -cell nicotinamide adenine dinucleotide (NAD) and subsequent histopathologic alteration of pancreatic islet β -cells.

Spontaneous ovine diabetes mellitus has not been reported. The sheep is a ruminant species with little dietary intake of glucose and only small fluctuations in plasma glucose with meals. The control pregnancy ewes showed no tendency toward an elevation of plasma glucose with advancing gestation. Abnormal carbohydrate metabolism in the streptozocin-treated ewes was reflected by the presence of fasting hyperglycemia and altered glucose tolerance. This altered glucose metabolism is due to profound maternal insulinopenia, which is a secondary effect of the destructive pancreatic β -cell action of streptozocin. The phasic insulin response reflects an initial depletion of long-term stores followed by loss of short-term preformed insulin on repeat challenge.

Fetal hyperglycemia, hyperinsulinemia, and increased weight were observed. Although not reaching statistical significance, the p value is highly suggestive of fetal hyperinsulinism. Insulin is a known fetal growth hormone and in the presence of increased fetal weight

increases the significance of the elevations noted in fetal insulin levels.

Anecdotally, we have observed hyperphagia, polyuria, and polydipsia in the streptozocin-treated ewes, features that are well reported in human diabetes mellitus. Impaired tissue integrity of placental cotyledons has been noted previously by our research department in this model.⁶

Alloxan, a pancreatic islet cell toxic agent, also has been used in the pharmacologic induction of diabetes. ⁷⁻⁹ Unlike streptozocin, alloxan is not as pancreatic β-cell specific and is often toxic to other organ systems. ¹⁰ The alloxan animal preparation is both hyperglycemic and hyperketonemic because of pancreatic α-cell and β-cell destruction. Transplacental passage of alloxan, because of its small molecular size, with destruction of the fetal pancreas has been reported. ¹¹ This limits the use of this agent to acute animal studies, which do not accurately simulate the usual human disease process.

Reynolds et al.12 demonstrated that streptozocin does cross the hemochorial placenta of the rhesus monkey to a limited degree but has no discernible effect on the fetal pancreas. In the streptozocin-treated rhesus monkey, Mintz et al.18 reported fetal hyperinsulinemia and appropriate fetal pancreatic responses to glucose stimuli. We observed hyperglycemia, hyperinsulinemia, and the preservation of the insulin/glucose ratio in fetuses of diabetic ewes, implying appropriate fetal pancreatic β-cell function. Attempts at chronic studies with administration of alloxan earlier in gestation have resulted in fetal growth restriction,9 presumably as a result of fetal pancreatic destruction and secondary fetal hypoinsulinemia. The degree of fetal hyperglycemia may increase progressively with time, and studies of the fetal pancreatic response to preconception administration of streptozocin are planned.

We have demonstrated that administration of streptozocin in midgestation to the pregnancy ewe creates a

large-animal model that is useful for investigating the effects of chronic maternal carbohydrate intolerance. The maternal effects are those of hyperglycemia, insulinopenia, and an abolition of the insulin response to a glucose load. The fetus is large for gestational age, has hyperglycemia, and has an elevation in basal insulin levels, all features that are observed clinically in the fetus of a woman with gestational diabetes.

We acknowledge Wil Morgan and The Upjohn Company for their assistance in this research.

The changing glycemic response to exercise during pregnancy

James F. Clapp III, MD, and Eleanor L. Capeless, MD

Cleveland, Ohio, and Burlington, Vermont

This study was designed to test the hypothesis that pregnancy reverses the nonpregnant hyperglycemic response to sustained exercise. Serial data were obtained from 75 exercising women. Before pregnancy, exercise produced an intensity-dependent increase in blood glucose that averaged 1.5 mmol/L at high intensities. By the eighth week this response was blunted and blood glucose increased only when exercise intensity exceeded 80% of maximum. At 15 weeks this progressed and was not associated with a change in either the insulin or catecholamine response. By the twenty-third week exercise produced a decrease in blood glucose that was no longer related to exercise intensity. We conclude that the hypothesis is correct and speculate that the early change in the response is related to decreased hepatic glucose release coupled with increased glucose oxidation. In late pregnancy this is probably accentuated by fetoplacental demands. (AM J OBSTET GYNECOL 1991;165:1678-83.)

Key words: Pregnancy, exercise, glucose

The change in blood glucose level that occurs during exercise represents a shift in the balance between splanchnic glucose production and peripheral glucose uptake.¹ When production exceeds uptake, blood glucose rises, and when uptake exceeds production, it falls. In exercising men the balance between production and uptake is variable and appears to be dependent on multiple factors such as food intake, catecholamine response, physical condition, and the type, intensity, and duration of the exercise.¹-⁵ Although detailed data are not available in women, it is probable that the relationships and mechanisms are similar.

During pregnancy the amount of maternal glucose available for fetoplacental uptake varies directly with maternal levels, and in large animal models maternal hypoglycemia is associated with fetal growth restriction. Thus a maternal hypoglycemic response to regular recreational exercise during pregnancy potentially could restrict fetal glucose availability and result in some degree of fetal growth restriction.

This potential concern has been reinforced by several findings. First, data obtained in a limited number of

subjects indicate that the consistent increase in blood glucose levels seen in response to recreational running in fit, nonpregnant women was initially blunted and then reversed after similar exercise sessions during pregnancy. Second, recreational athletes who continued a regular running or aerobics regimen in late pregnancy were delivered at term of infants with morphometric evidence of mild asymmetric growth restriction.

The current study was undertaken to explore the relationship between pregnancy and the glycemic response to exercise in greater detail. It was designed to test the hypothesis that when fit female recreational athletes continue to exercise during pregnancy the preconceptional hyperglycemic response to field exercise is reversed. The findings support the hypothesis and suggest that the pattern of food intake before, during, and after exercise may need to be altered in the recreational athlete during pregnancy.

Methods

After obtaining informed consent in accord with institutional guidelines, 75 healthy, fit, female recreational athletes who either ran (n=40) or performed aerobics (n=35) three or more times each week were enrolled for prospective study. Each subject was studied serially before conception and every 6 to 8 weeks throughout pregnancy. All subjects maintained their regular weekly exercise regimens above 60% of their preconceptional performance levels throughout pregnancy. All pregnancies were singleton, accurately dated, and clinically normal. Total pregnancy weight gain (mean 12.7 kg; range 7.3 to 17.3 kg) was adequate and agreed with the reported approximate caloric intake at the various time points of study (mean 40

kcal/kg; range 30 to 55 kcal/kg). The caloric mix was typical for an exercise populace (high complex carbohydrate, low fat, adequate protein).

To reproduce the conditions of each individual's exercise sessions outside the laboratory, all subjects were encouraged to eat their usual diet and were studied at a time relative to food intake that coincided with their regular exercise regimen (90 to 270 minutes after food intake). In 70 of the 75 subjects the study protocol began with 10 minutes of rest followed by 20 minutes of representative exercise. A free-flowing forearm venous blood sample was obtained at the end of the rest and exercise period for determination of glucose, insulin, and norepinephrine content. The exercise consisted of either a treadmill run or a standardized aerobics regimen and was conducted at a representative exercise intensity for each individual at each given time point in pregnancy. Daily exercise intensity was monitored with a portable heart rate monitor,10 and the average exercise heart rate for the preceding week was maintained during each laboratory exercise session. Exercise intensity was determined by monitoring oxygen consumption for the latter half of the exercise session and was expressed as a percentage of each individual's preconceptional maximum capacity.9

In the remaining five subjects an indwelling forearm venous sampling catheter was placed before study and free-flowing blood samples were obtained every 15 minutes throughout the protocol. The protocol began with 30 minutes of standing rest followed by a 45-minute, intensity-controlled, uphill treadmill walk and ended with 30 minutes of sitting rest. On each test occasion, the exercise intensity, determined by oxygen consumption, was maintained at a level equivalent to 50% of each individual's preconceptional maximum capacity.

Glucose levels were determined in duplicate on whole blood with a glucose oxidase method.11 Serum insulin was measured with a double antibody radioimmunoassay, modified from that described by Starr et al.,12 with interassay and intraassay coefficients of variation of <10% and <5%, respectively. Blood samples for norepinephrine were collected in chilled tubes containing ethylene glycol-bis(β-amino-ethyl ether)N,N,N',N'-tetraacetic acid and glutathione and stored at -70° C until analysis by high-performance liquid chromatography with a modification of the method of Kontur and Dawson¹⁸ (sensitivity 15 pg/ml; coefficient of variation <5%).

The data were initially grouped by the intensity of the exercise and analyzed for significant change from rest and from preconceptional values at each study point, by means of analysis of variance and Duncan's multiple range test. Linear regression was used to detect relationships between exercise intensity and the change in glucose. Significant changes over time were sought with analysis of variance and Duncan's multiple range test. Significance was set at the p < 0.05

Results

The effect of 20 minutes of running or aerobics on blood glucose levels under conditions similar to those experienced during daily exercise in the field are shown in Table I. The number of subjects exercising within a given intensity range is not shown, as it changed from one time point to another. Before conception 16 exercised below 60% of their maximum and 33 exercised above 69% of their maximum, with an overall average exercise intensity of 68% of maximum. At 8 weeks 25 exercised below 60% and 25 above 69% of their maximum, with the average overall value being 64% of maximum capacity. At 15 and 23 weeks the size of the low-intensity group was stable at 25, but only 18 exercised above 69% of maximum with mean intensities of 63% and 61% of maximum, respectively. After the thirtieth week, 29 exercised at <60% of maximum while 18 continued to exercise above 69% of maximum, and the overall mean intensity was maintained at 62% of maximum capacity.

Before pregnancy postexercise blood glucose levels exceeded preexercise values 96% of the time and the increase was significant at all exercise intensities. The average postexercise elevation varied directly with exercise intensity over a blood glucose range of 3.5 to 7.95 mmol/L at exercise intensities between 42% and 87% of maximum (change in glucose = -2.02 $\text{mmol/L} + 0.042 \times \text{percent maximum}, r = 0.5425$). This predicts that blood glucose will rise at exercise intensities in excess of 48% of maximum capacity at a rate of 0.44 mmol/L for each 10% increase in exercise intensity above that level. At <60% of maximum intensity the increase averaged 0.32 ± 0.10 mmol/L (mean \pm SEM) rising to 1.54 \pm 0.29 mmol/L at intensities >80% of maximum.

By the eighth week of gestation the response changed, with postexercise glucose levels exceeding preexercise values <40% of the time. A significant increase postexercise occurred only when intensity exceeded 80% of maximum capacity, with the average increase in blood glucose falling by 33% to 1 mmol/L. There was a significant downward shift in both the slope and the intercept of the relationship between exercise intensity and the change in blood glucose (change in glucose = $-2.04 \text{ mmol/L} + 0.034 \times \text{percent max}$ imum, r = 0.4868). This predicts that blood glucose will rise only at exercise intensities >63% of maximum capacity at a rate of 0.34 mmol/L for each 10% increase in intensity above that level. This change suggests that a shift in the relationship between hepatic glucose pro-

duction and peripheral use during exercise begins early in pregnancy.

In the fifteenth week the change progressed with postexercise glucose levels exceeding preexercise levels <25% of the time. Postexercise values were significantly lower ($-0.62 \pm 0.12 \text{ mmol/L}$) than those observed preexercise at intensities <60% of maximum capacity and were unchanged at all higher intensities. The regression equation (change in glucose = $-2.04 \text{ mmol/L} + 0.027 \times \text{percent}$ maximum, r = 0.4494) predicts that exercise in the fifteenth week of gestation will increase blood glucose only at intensities >76% of maximum capacity at a rate of only 0.27 mmol/L for each 10% increase in intensity above that level.

By the twenty-third week, postexercise glucose levels rose <20% of the time and a significant decrease in glucose levels of similar magnitude (-0.60 ± 0.15 mmol/L) occurred after exercise at all exercise intensities <70% of maximum capacity. Regression of exercise intensity versus the change in glucose level was no longer significant (r=0.1988) with a slope of 0.010. After the thirtieth week, postexercise glucose levels rose <10% of the time, a significant decrease in glucose levels occurred after exercise at all exercise intensities <80% of maximum capacity, and the relationship between exercise intensity and the change in blood glucose remained nonsignificant.

In the subjects who maintained their exercise intensity at <60% of maximum capacity, which approximates the recommendations of the American College

of Obstetricians and Gynecologists, ¹⁴ exercise was associated with a consistent, significant decrease in blood glucose from the fifteenth week onward. In the twenty-third, thirtieth, and thirty-seventh week >20% of the individuals had postexercise values ≤3.3 mmol/L with mean postexercise levels approximating 3.9 mmol/L.

Table II details the serial changes observed in the insulin and norepinephrine levels after 20 minutes of representative exercise during pregnancy. Unfortunately, between 10 (14%) and 16 (23%) of the sample sets were partially incomplete at each time point, but their distribution over the various intensity ranges was random. Serum insulin levels decreased significantly after exercise at all time points, and the magnitude was unchanged by increasing exercise intensity. Both preexercise and postexercise levels remained at or near those observed before conception through the twentythird week. After the thirtieth week, both the preexercise and postexercise values rose significantly above the concentrations observed before pregnancy, reflecting the development of relative insulin resistance in all subjects in late pregnancy. Preexercise norepinephrine levels did not change significantly with advancing gestation. However, the mean postexercise level fell significantly in the eighth week and remained at that level for the remainder of the pregnancy. This appeared to be due to the 4% to 7% decrease in mean exercise intensity during pregnancy. When the raw data were corrected for exercise intensity, a significant decrease from preconceptional levels was seen only after the

thirtieth week at exercise intensities >69% of maximum capacity.

Table III details the serial changes observed in the respiratory exchange ratio during exercise. It increased significantly by the eighth week at all exercise intensities, and the elevation was maintained at all intensities through the fifteenth week. Thereafter, changes in the respiratory exchange ratio became nonsignificant at the higher intensities, but a significant increase in the ratio was maintained at exercise intensities <69% of maximum capacity. With Lusk's calculation,15 the pregnancy-associated increase in the ratio approximates a 5% to 7% increase in the fractional oxidation of carbohydrate during exercise in pregnancy.

The serial changes in the five subjects who exercised at a constant intensity (50% max) throughout pregnancy were similar to those observed in the larger group. Before pregnancy, a small but significant increase in blood glucose ($+0.35 \pm 0.06 \text{ mmol/L}$) was observed by the thirtieth minute of exercise, with a gradual return to preexercise levels during recovery. In the eighth week this did not occur and by the fifteenth week the response was reversed with a significant decrease in blood glucose ($-0.62 \pm 0.08 \text{ mmol/L}$) by the fifteenth minute of exercise that persisted (-0.46to -0.64 mmol/L) for the remainder of the exercise and recovery period (60 minutes). A similar pattern was observed at 23, 30, and 37 weeks, with average decreases in blood glucose level during exercise and

recovery of -0.63, -0.56, and -0.61 mmol/L at the three respective time points of study. Norepinephrine levels at rest, during exercise, and at recovery were similar to those observed before conception until the thirtieth week. Thereafter, levels at rest and during exercise were significantly decreased (rest, 727 to 457 and 529 pg/ml; exercise, 1240 to 848 and 782 pg/ml), but the absolute change from rest to exercise was significantly decreased only at 37 weeks (change in norepinephrine, 513 to 271 pg/ml). Table IV details the serial changes in insulin and the respiratory exchange ratio during exercise in these five subjects. Again there was no significant change in insulin levels until the thirtieth week, when the levels both at rest and during exercise increased. The respiratory exchange ratio at standing rest increased significantly after the thirtieth week, but the values during exercise were increased significantly above preconceptional values throughout pregnancy ($+0.056 \pm 0.006$ units).

Comment

These serial data, gathered under conditions designed to mimic an individual's daily habits (dietary, temporal, exercise type, and intensity), demonstrate that the nonpregnant hyperglycemic response to recreational running and aerobics is initially blunted and then reversed early in the course of pregnancy. Because weight gain, caloric intake, and caloric mix were relatively constant and adequate, this suggests that some of

^{*}Significantly different from value before pregnancy, p < 0.05.

^{*}Significantly different from value before pregnancy, p < 0.05.

the metabolic adaptations induced by pregnancy alter the balance between hepatic glucose production and peripheral use, which becomes apparent only when peripheral use is increased. A similar hypoglycemic shift, the so-called accelerated starvation of pregnancy,¹⁶ is another example of this phenomenon.

While the underlying mechanism for this shift during pregnancy is unclear, the increase in the respiratory exchange ratio during exercise in early pregnancy suggests that this may be due in part to a pregnancy-associated increase in the fractional use of carbohydrate by muscle during exercise. The superimposition of the constant and ever-increasing glucose use by the growing placenta and fetus also must increase the demand for glucose during exercise in late pregnancy. 6, 7, 17 This additional demand is reflected in the increase in the respiratory exchange ratio at rest observed after the thirtieth week. The combination of increased glucose use by both exercising muscle and the fetoplacental unit probably is responsible for both the increase in the magnitude and the consistency of the hypoglycemic response during exercise in late pregnancy. In addition, the fact that there is no change in either the insulin or catecholamine response, coupled with the intensity dependence of the glycemic response reversal early in gestation, suggests that during exercise there is also a pregnancy-associated decrease in hepatic glucose production that is not apparent at rest.17 This physiologic change also should alter glucose homeostasis, favoring a fall in blood glucose levels during exercise. A definitive answer to both possibilities (a pregnancy-associated increase in fractional glucose use by exercising muscle and a decrease in hepatic glucose production during exercise) will require further serial studies with the use of stable isotope infusion.

The fact that the pregnancy-associated increase in the respiratory exchange ratio during exercise was consistently abolished at high exercise intensities with advancing gestation is an apparent contradiction and requires explanation. Unfortunately we do not have all the data necessary to identify the underlying mechanism. However, the consistency of the data suggests that it is real and not an interpretive error. The possibility that carbon dioxide retention occurred during highintensity exercise in late pregnancy (which would factitiously lower the ratio) is unlikely because minute ventilation progressively increased and expired carbon dioxide concentration decreased during pregnancy. Thus we are left with the speculation that muscle glycogen stores at rest are significantly reduced in late pregnancy (possibly because of the increasing requirements of the placenta and fetus) with a resultant depletion of muscle glycogen earlier during high-intensity

exercise. When combined with the presumed suppression of hepatic glucose production and fall in blood glucose levels, this change could easily limit glucose availability to exercising muscle earlier in the latter half of pregnancy. A definitive answer would require serial muscle biopsy in a limited number of subjects during protracted high-intensity exercise.

In terms of fetoplacental substrate availability, the data indicate that relatively brief, low- and moderateintensity recreational exercise rapidly lowers maternal blood glucose levels by 0.5 to 0.7 mmol/L on average and that the decrease persists for as much as 30 minutes after exercise. Whether an intermittent change of this degree is sufficient to significantly restrict fetal substrate supply and ultimately growth rate is currently unclear. However, the observation that this degree of running and aerobics in late pregnancy was associated with morphometric evidence of asymmetric growth restriction suggests that, coupled with other physiologic changes (such as a probable reduction in placental bed blood flow), it may have an appreciable effect that potentially has therapeutic value.7, 10 For example, >70% of the exercise-associated decrease in birth weight was due to a 220 gm reduction in body fat, suggesting that reduced fat cell number could have prophylactic value. Likewise, regular, low- to moderate-intensity exercise in late pregnancy has been shown to be as effective as insulin in maintaining euglycemia in a limited number of subjects. 18, 19 Given a larger experience, it is likely that it will also be shown to reduce birth weight, which should reduce morbidity in the large-for-gestational age infant.

Finally, it is unfortunate that there are no background data addressing the factors that influence glucose metabolism during exercise in nonpregnant women. This study suggests that fit women who exercise regularly may have a different response from men,²⁻⁵ because the response to sustained but short-duration exercise is consistently a hyperglycemic one whose magnitude is intensity dependent.

In summary, the preconceptional hyperglycemic response to running and aerobics, seen in female recreational athletes, is reversed during pregnancy. The reversal is initially intensity dependent and does not appear to be related to changes in either insulin or norepinephrine response. The data suggest that it may reflect a pregnancy-associated decrease in hepatic glucose production and a pregnancy-associated increase in fractional glucose use by muscle during exercise. In late pregnancy the increased peripheral use of glucose is further increased by the demands of the fetoplacental unit, which magnify the change in blood glucose response and probably obscure its intensity dependence.

The relative hypoglycemia associated with exercise persists for an as yet undefined period of time after exercise and may influence fetal growth.

Bound volumes available to subscribers

Bound volumes of the American Journal of Obstetrics and Gynecology are available to subscribers (only) for the 1991 issues from the Publisher, at a cost of \$61.00 for domestic, \$88.27 for Canada, and \$84.00 for international for Vol. 164 (January-June) and Vol. 165 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the IOURNAL name, volume number, and year stamped in gold on the spine. Payment must accompany all orders. Contact Mosby-Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

The changing thermal response to endurance exercise during pregnancy

James F. Clapp III, MD

Burlington, Vermont

This study was designed to test the hypothesis that the thermal response to endurance exercise is altered by the thermal adaptations to pregnancy. Accordingly, rectal temperature was monitored in 18 recreational athletes before, during, and after 20 minutes of continuous exercise before conception and every 6 to 8 weeks during pregnancy. Mean exercise intensity was 64% of Vo₂ max before conception and did not change during pregnancy. However, the peak rectal temperature reached during exercise decreased by 0.3° C at 8 weeks and then fell at a rate of 0.1° C per lunar month through the thirty-seventh week. This appeared to be related to changes in resting temperature, thermal mass, sweating threshold, and venous capacitance that began early in pregnancy. These data suggest that the magnitude of any exercise-associated thermal stress for the embryo and fetus is markedly reduced by the maternal physiologic adaptations to pregnancy. (AM J OBSTET GYNECOL 1991;165:1684-9.)

Key words: Exercise, pregnancy, temperature

Female recreational runners have been shown to routinely have an increase in rectal temperature to 39° to 39.5° C during exercise,1,2 and under conditions of high environmental temperature and humidity, the increase exceeds this level at much lower exercise intensities.3 During pregnancy an increase in maternal rectal temperature to these levels places the embryo and fetus at theoretical teratogenic and metabolic risk.4 For this and other reasons, sanctioned guidelines recommend that exercise duration be limited to 15 minutes and that pulse rate be kept under 140 during pregnancy.5 However, the data currently available suggest that the thermoregulatory adaptations to both regular exercise and pregnancy maintain the level of thermal stress below the level of concern when recreational runners continue to run at higher intensities for more protracted periods of time during pregnancy.1, 6, 7

The current study was undertaken to explore these early observations through serial studies of well-conditioned recreational athletes who maintained a regular exercise regimen of running, aerobics, or cycling throughout pregnancy. It was specifically designed to

test the hypothesis that the thermal response to endurance exercise is altered by the thermal adaptations to pregnancy.

Material and methods

Subjects. Eighteen well-conditioned recreational athletes were studied during their chosen form of exercise (eight ran, seven performed aerobics, and three cycled) before conception and every 6 to 8 weeks during the subsequent pregnancy. They were between the ages of 27 and 34 years, in excellent health, of upper-middle or upper socioeconomic status, and worked regularly outside the home. All had been exercising regularly (at least three times a week for ≥ 30 minutes) for ≥ 2 years before study, were fit at enrollment as assessed by percent body fat (range, 10% to 19%) and Vo₂max (range, 47 to 67 ml·kg⁻¹·min⁻¹), and maintained a regular exercise regimen throughout pregnancy. Exercise performance during pregnancy was monitored and averaged $85\% \pm 8\%$ (range, 68% to 104%) of preconceptional performance. All pregnancies were singleton, clinically normal, and accurately dated.

Experimental protocol. On each occasion testing was conducted 1 to 3 hours after eating, the subject wore the same exercise apparel, and body weight was obtained on a balance-beam scale to the nearest 100 gm after voiding. Then measurements of rectal temperature and oxygen consumption were obtained during an initial 10-minute period of quiet standing or sitting (cyclists only) rest and during the 20 minutes of exercise and 10 minutes of recovery that followed. Although absolute workload varied from session to session, during each exercise session the treadmill speed and grade were held constant for the runners, the cyclists biked

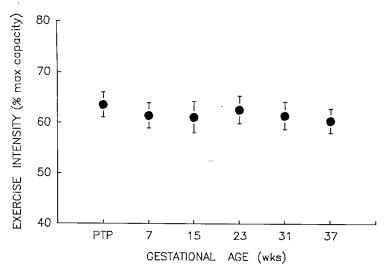

Fig. 1. Exercise intensity attained at each test time point before and during pregnancy. Data are presented as mean ± SEM. PTP, Before pregnancy.

on a Monark cycle ergometer at a constant pedal frequency and load, and the remainder followed a specially designed constant intensity aerobics routine that was displayed on a video monitor. Environmental conditions were held relatively constant for all tests (dry bulb temperature, 19° to 21° C; relative humidity, 30% to 55%; no added air flow).

Measurement techniques. Rectal temperature was monitored continuously and recorded each minute throughout the study with a precalibrated YSI thermistor (Yellow Springs Instrument Co., Yellow Springs, Ohio) with a reproducibility of $\pm 0.02^{\circ}$ C that was held in place 13 cm above the anal verge by taping it to a perineal pad. Oxygen consumption was monitored continuously throughout the last 10 minutes of exercise with a respiratory calorimetry system with a reproducibility under test conditions of $\pm 3\%$.8.9 The onset of sweating was determined by each individual's subjective sensation of sweating (occurs within 30 seconds of that determined with a resistance hygrometer sweat capsule). Exercise intensity was calculated from the mean oxygen consumption during the last 10 minutes of exercise and expressed as a percentage of Vo₂max, which was determined preconceptionally with a constant speed, progressive grade treadmill protocol.8,9

Statistics. The data were analyzed by means of repeated-measures analysis of variance and linear regression. Significance was set at the 0.01 level.

Results

As shown in Fig. 1, exercise intensity did not change significantly from one study to the next, with mean value for the group ranging between 61% and 64% of Vo₂max over the six study periods. However, the respiratory exchange ratio during exercise rose significantly (p < 0.01) from 0.86 ± 0.03 (mean ± SD) before conception to 0.91 ± 0.03 by the seventh week, representing a 1.5% increase in the caloric equivalent for oxygen. It remained near that level for the remainder of the pregnancy.

In spite of the evidence of consistent or slightly increased energy expenditure in the exercise sessions during pregnancy, the maximum rectal temperature reached during exercise (Fig. 2) fell 0.3° C by the seventh week of pregnancy and then continued to decrease linearly at an average rate of 0.1° C per lunar month. The range of individual R2s for this decremental change was 0.69 to 0.99 with a mean group R2 of 0.890 ± 0.094. This longitudinal change was significant at the p < 0.0001 level.

In addition, beginning early in pregnancy, there was a steady increase in body weight (Fig. 3) that averaged 1.7 kg per lunar month (group $R^2 = 0.994$, weight = $59.8 + 1.75 \text{ kg} \cdot \text{lunar month}^{-1}$) and a steady fall in rectal temperature at rest (Fig. 4) that averaged 0.05° C per lunar month (group $R^2 = 0.983$, temperature = 37.64° C - 0.05° C · lunar month⁻¹). Both were significant at the p < 0.0001 level. As shown in Fig. 5, the rectal temperature at which sweating began during exercise fell progressively at a rate of 0.08° C per lunar month ($R^2 = 0.993$, temperature = $37.80 - 0.09^{\circ} \text{ C} \cdot \text{lunar month}^{-1}$) and the increase in rectal temperature between rest and the onset of sweating decreased abruptly by the seventh week (0.19° to 0.06° C), as did the temperature difference between rest and the peak temperature during exercise (0.80° to 0.54° C). Again, these changes were highly significant.

Finally, before conception rectal temperature consistently began a linear increase during the first 2 minutes of exercise. This disappeared during pregnancy and actually reversed itself for the first few minutes of ex-

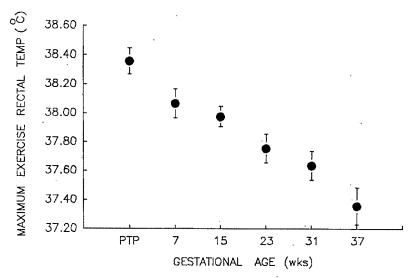

Fig. 2. Maximum rectal temperature recorded during exercise before and during pregnancy. Data are presented as mean \pm SEM. *PTP*, Before pregnancy.

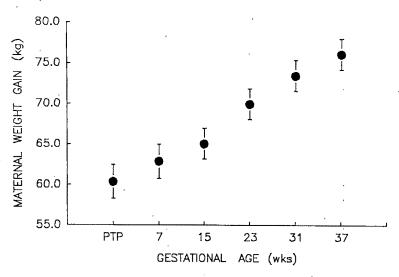

Fig. 3. Longitudinal changes in body weight during pregnancy. Data are presented as mean \pm SEM. *PTP*, Before pregnancy.

ercise beginning in the eighth week. This became more pronounced with advancing gestation. Thus in the thirty-seventh week rectal temperature fell 0.1° C at the onset of exercise and did not return to control levels until minute 8 to 10 of exercise.

The overall magnitude of the impact of these factors on the potential for embryonic and fetal thermal stress was assessed by calculating the area under the rectal temperature curve that exceeded 37.6° C during the 20 minutes of exercise and the 10 minutes of recovery and by expressing it in degree min⁻¹. The area calculated from the data obtained before conception was compared with that obtained during the seventh and thirty-first weeks of gestation. Before conception the area was 12.3 degree min⁻¹, in the seventh week the

value was only 35% (4.3 degree \cdot min⁻¹) of the preconceptional value, and it was 8% (1.0 degree \cdot min⁻¹) at 31 weeks.

Comment

These data support the initial hypothesis and indicate that multiple thermal adaptations to pregnancy alter both the magnitude of the thermal response and the peak temperature attained when continuous, moderate- to high-intensity exercise is performed during pregnancy. Furthermore, as all the changes noted appear early in pregnancy and progress, they appear to provide thermal protection for the embryo and fetus.

With one exception, these findings are similar to those reported from this laboratory earlier.¹ The ex-

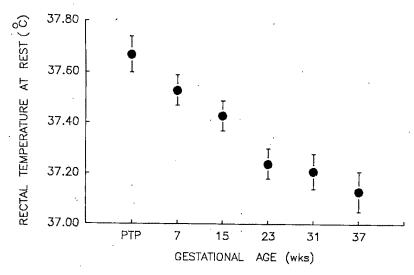

Fig. 4. Rectal temperature recorded at standing rest before exercise before and during pregnancy. . Data are presented as mean ± SEM. PTP, Before pregnancy.

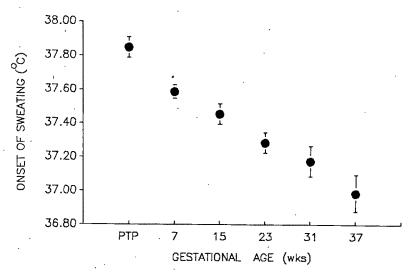

Fig. 5. Rectal temperature at which subjective onset of sweating occurred before and during pregnancy. Data are presented as mean ± SEM. PTP, Before pregnancy.

ception is that the decrease in resting temperature was not observed in the earlier study. The explanation probably lies in the fact that environmental temperature was a bit lower in the current study, which probably enhanced heat loss with a resultant lowering of rectal temperature. Indeed, other data10 suggest that it may have been lowered to the point where it actually may have induced heat generation. It is probable that either the lack of preconceptional values coupled with differences in exercise intensity or environment also explain the discrepancy between the current findings and the data obtained by Jones et al.6 in an apparently similar small group of women.

The data indicate that multiple pregnancy-associated adaptations contributed to the modified thermal response. First, maternal weight gain increased the quantity of heat necessary to raise the body temperature the same amount by 1% to 1.5% at 7 weeks and by 12% to 14% near term simply because of the thermal inertia created by the increased tissue mass.11 This increase in thermal inertia was further accentuated by the pregnancy-associated decrease in rectal temperature at the onset of exercise, discussed in detail below. Second, the progressive fall in resting rectal temperature and the more pronounced fall in the rectal temperature at which sweating began suggests that these two thermoregulatory set points decrease progressively with advancing gestation. Physiologically, these changes are not unusual, as they normally occur nocturnally12 and as part of the overall thermal acclimation to regular exercise in a hot, humid environment.7 Presently the mechanisms underlying these changes are unclear. However, they are felt to represent the normal adaptive response to changes in nonthermoregulatory metabolic heat production and have both central and peripheral components. As pregnancy is associated with an increase in metabolic rate, these changes probably represent a normal physiologic response to increased heat production. In any case, they clearly diminish the impact of any additional heat generation and improve the ability to dissipate heat.

Given that basal body temperature during pregnancy remains elevated until the mid second trimester, ^{18, 14} the fall in resting temperature in early pregnancy was a surprise. The discrepancy suggests that the decremental change was obscured in the basal body temperature studies until later in the pregnancy by the thermal insulation inherent in the "basal conditions" described. In the current study the clothing and environmental temperature offered no such insulation and would encourage heat loss, allowing early recognition of the thermal adaptations to the increased heat production of pregnancy.

The marked pregnancy-associated increase in skin temperature and blood flow,15-17 coupled with the approximate 3 L increase in minute ventilation, should have improved convective, radiant, conductive, and evaporative avenues of heat loss. Although not measured in this study, the pregnancy-associated increase in distal extremity temperature at rest is reported to exceed 4° C and hand, forearm, and calf blood flows double. All else being equal, this should have improved the efficiency of heat transfer from the body core to the skin and increase convective and radiant heat loss from the extremities by between 12% and 17%.18 However, as the pregnancy-associated change in mean skin temperature has not been measured and the distal extremities only contribute 15% to mean skin temperature, it is likely that the overall increase in convective and radiant heat loss from the skin would have been no more than 5% to 7%. The percentage increase in evaporative heat loss from the respiratory tract should have varied inversely with minute ventilation. The pregnancy-associated rise in minute ventilation should have increased respiratory evaporative heat loss between 25% and 40% at rest, but, during exercise at the levels encountered in the current study, it would have increased only 5% to 8%.

The impact of these various adaptations on overall heat dissipation at the ambient temperature used in the current study can be approximated using the partitioning of heat loss estimates obtained in nonpregnant individuals. Before pregnancy, assuming a weight of 55 kg, a rise in core temperature of 0.8° C, a power output of 700 W (10 kcal/min) from exercise and an ambient temperature of 19° to 21° C, approximately 15% (100 W) of the heat generated should be retained

to account for the increase in core temperature. Of the remainder, 40% should be lost to the environment by convection (240 W), 5% by radiation (30 W), 5% as respiratory evaporative loss (30 W), and 50% by the evaporation of sweat (300 W). During the seventh week of pregnancy the thermal adaptation of a fall in resting core temperature (0.1° C) coupled with the increase in weight (3 kg) provided an additional amount of thermal inertia which should have buffered approximately 2% (15 W) of the heat generated before core temperature returned to its preconception resting level. The remaining increase in core temperature (0.44° C) should have stored an additional 9% (63 W) of the heat produced. Thus, at 7 weeks, total maternal heat storage should have decreased by approximately 22%. The increase in skin temperature and skin blood flow should have increased convective heat loss by approximately 5% to 252 W and radiant heat loss to 32 W. Evaporative loss from the lungs should have increased approximately the same amount (32 W), whereas, in spite of the lower body temperature, evaporative loss by sweating should have increased slightly, to 306 W. This could not have occurred without the observed downward shift in the sweating threshold. By the thirty-first week the overall decrease in resting core temperature of 0.43° C, coupled with the initial 0.1° C fall in core temperature and the 14 kg increase in body weight, should have provided an overall increase in thermal inertia, which by itself would buffer approximately 13% (89 W) of the heat generated in elevating core temperature to preconception resting levels. By this time point, the efficiency of convective heat loss should have increased approximately 7% to about 257 W, with the avenues of radiant and respiratory evaporative heat loss continuing to account for approximately 64 W. As maximum core temperature only rose to the value recorded at rest before pregnancy (37.65° C%), the remainder of the power generated (290 W) should have been lost as heat through sweat evaporation. Again this was possibly due to an overall downward shift in the sweating threshold, which actually exceeded the shift observed in resting core temperature (0.68° vs 0.43° C).

Finally, the initial fall in rectal temperature at the onset of exercise during pregnancy is puzzling but suggests that an increase in venous capacitance probably occurs early in pregnancy. With this change, additional blood would pool at rest in the periphery and cool down. At the onset of exercise its return to the central circulation would decrease central temperature and effectively buffer the initial heat generated. A similar response has been observed by Hong and Nadel¹⁹ during exercise in the cold.

In summary, in fit women who continue a regular exercise program during pregnancy, the adaptations to pregnancy appear to modulate the thermal response to exercise by several mechanisms. First, a pregnant woman's thermal inertia is increased as a result of pregnancy-associated progressive decrease in resting temperature that is magnified at the onset of exercise by the return of an increased volume of cool blood from the periphery and a progressive increase in body mass. Second, a downward shift in the central thermal threshold for sweating allows evaporative heat loss to proceed at lower core temperatures. Third, the pregnancy-associated increase in skin blood flow and skin temperature enhances heat transfer from the core to the skin and increases the thermal gradient between the individual and her environment, creating a significant increase in heat loss through convection and radiation. Finally, the rise in minute ventilation slightly increases heat loss from the respiratory tract. As a result of these changes, the maximum rectal temperature attained during 20 minutes of sustained exercise that generates approximately 10 kcal/min of heat is progressively reduced. In early pregnancy the maximum rise is reduced by >30%, progressing to >70% near term.

Maternal levels of prostacyclin, thromboxane, vitamin E, and lipid peroxides throughout normal pregnancy

Yuping Wang, MD,^{a,b} Scott W. Walsh, PhD,^a Jingde Guo, MD,^b and Junyan Zhang, MD^b Richmond, Virginia, and Harbin, People's Republic of China

In normal pregnancy the vasodilating actions of prostacyclin and the antioxidant activity of vitamin E are important for normal physiologic function. Thromboxane and lipid peroxides oppose these actions by promoting vasoconstriction and peroxidation reactions, respectively. An imbalance between thromboxane and prostacyclin and between lipid peroxides and antioxidant activity is implicated in pathologic states such as preeclampsia. We hypothesized that in normal pregnancy there would be a balance in the ratios of prostacyclin to thromboxane and of vitamin E to lipid peroxides that would favor prostacyclin and vitamin E. Blood samples were collected from normally pregnant women throughout gestation and analyzed for prostacyclin, thromboxane, vitamin E, and lipid peroxides. Serum levels of lipid peroxides remained relatively stable throughout gestation, but the levels of vitamin E progressively increased. Plasma levels of prostacyclin progressively increased with advancing gestation, whereas levels of thromboxane progressively decreased. Therefore the ratios of both prostacyclin/thromboxane, and vitamin E/lipid peroxides progressively increased during pregnancy. The increase in the ratios was highly correlated, r = 0.94. We conclude that the changes in the maternal concentrations of these compounds and the progressive increase in the ratios of prostacyclin/thromboxane and vitamin E/lipid peroxides suggest that the vasodilating actions of prostacyclin and the antioxidant activity of vitamin E are progressively favored with advancing gestation in normally pregnant women. (AM J OBSTET GYNECOL 1991;165:1690-4.)

Key words: Lipid peroxides, vitamin E, thromboxane, prostacyclin, pregnancy

Prostacyclin and thromboxane are metabolites of arachidonic acid and exert diverse biologic effects. Prostacyclin is a potent vasodilator and inhibitor of platelet aggregation. During pregnancy it also decreases uterine contractility and increases uteroplacental blood flow. Thromboxane has the opposite effects of prostacyclin. A balance between the actions of prostacyclin and thromboxane is important in maintaining vascular function and platelet stability during normal pregnancy. An imbalance between their actions in preeclampsia is thought to play an important pathologic role in this disorder.¹

Lipid peroxides are toxic compounds that can damage enzymes, proteins, and cell membranes.^{2, 3} Lipid peroxides are related to the synthesis of prostaglandins because they are produced during the enzymatic conversion of arachidonic acid to prostacyclin, thromboxane, and other metabolites. Lipid peroxides also affect the synthesis of prostaglandins. At low concentrations

lipid peroxides stimulate cyclooxygenase, but when their concentrations increase above normal, they inhibit prostacyclin synthase and cyclooxygenase to decrease prostacyclin synthesis. Thromboxane synthase is not affected by lipid peroxides.

The toxic actions of lipid peroxides are opposed by vitamin E, which is a free radical scavenger and thus prevents the formation of lipid peroxides. It functions as an in vivo antioxidant that protects tissue lipids from free radical attack,^{2, 7-9} thereby stabilizing cell membranes.¹⁰

Because of the opposing biologic actions of these compounds, we hypothesized that in normal pregnancy there would be a balance in the ratios of prostacyclin to thromboxane and vitamin E to lipid peroxides that would favor the concentrations of prostacyclin and vitamin E and thus presumably their biologic actions. To test this hypothesis maternal blood samples were collected throughout gestation from normally pregnant women, and the samples were analyzed for prostacyclin, thromboxane, lipid peroxides, and vitamin E.

Material and methods

Blood was collected from a total of 82 normally pregnant women and from 30 nonpregnant women. Institutional approval was obtained to conduct this study. Pregnancy was divided into 4-week intervals, and blood was collected from approximately 10 women for each interval. All subjects were between 20 and 40 years old,

and none were taking aspirin or receiving vitamin E therapy.

Venous blood samples (6.0 ml) were collected from the median cubital vein before 9 AM. Two milliliters of each sample was allowed to clot, was centrifuged, and was used as serum samples for lipid peroxide and vitamin E analysis. Four milliliters of each sample was drawn into a syringe containing 0.2 ml of 2% heparin and 0.05% indomethacin and used as plasma samples for determination of 6-keto-prostaglandin (PG) F₁₀ and thromboxane (Tx) B₂ by radioimmunoassay.

Lipid peroxides were estimated by the method of Yagi,11 which measures thiobarbituric acid-reactive products and expresses the data in terms of malondialdehyde. Four milliliters of 1/12N sulfuric acid and 0.5 ml of 10% phosphotungstic acid were added to 20 μl serum and mixed thoroughly. After centrifugation at 3000 rpm for 10 minutes, the liquid phase was decanted. Two milliliters of 1/12N sulfuric acid and 0.3 ml of 10% phosphotungstic acid were added to each sample, mixed, and centrifuged again. The liquid phase was decanted. Four milliliters of double-distilled water and 1.0 ml of TBA reagent (0.67% 2-thiobarbituric acid/acetic acid, 1:1) were then added to each sample, mixed, and heated at 95° C for 1 hour. Samples were cooled with tap water. Five milliliters of n-butyl-alcohol was added, and the samples were vigorously shaken for I minute and centrifuged. The n-butyl-alcohol phase, which contained the lipid peroxides, was used for malondialdehyde analysis with a Shimadzu FR-540 fluorospectrophotometer (Kyoto) with excitation at 515 nm and emission at 553 nm. Tetramethoxy propane (TCI, Tokyo Kasei, Japan) was used as standard and doubledistilled water as control. Recovery of exogenously added standard was 98%, and the coefficient of variation for the assay was 6.5%. Assay of varying sample volumes resulted in linear responses parallel to the standard curve.

Vitamin E was determined by fluorometric measurement of tocopherol in serum as described by Abe and Katsui.¹² One milliliter of double-distilled water and 1.0 ml of ethanol were added to 0.2 ml of serum and mixed thoroughly. Five milliliters of n-hexane was added and the samples were vigorously shaken for 1 minute. Samples were centrifuged at 1000 rpm for 5 minutes, and the hexane phase was separated and analyzed for tocopherol with a Shimadzu FR-540 fluorospectrophotometer at an excitation of 295 nm and an emission of 320 nm. DL-α-Tocopherol (E. Merck, West Germany) was used as standard and double-distilled water as control. Recovery of exogenously added vitamin E was 95%, and the coefficient of variation for the assay was 5.5%. Assay of varying sample volumes resulted in linear responses parallel to the standard curve.

Prostacyclin and thromboxane concentrations were estimated by specific radioimmunoassay of their stable metabolites, 6-keto-PGF₁₀ and TxB₂, respectively, similar to analysis with previously described assays.1 The assays consisted of competitive binding of radioactive and natural TxB₂ or 6-keto-PGF₁₀ to specific antibodies. Dextran-coated charcoal was used to separate the bound from the free fraction. Radioimmunoassay kits were obtained from the Department of Pharmacology, Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences (Beijing). The cross-reactivity of the TxB₂ antibody was PGE₂ <0.5%, PGE₁ 0.08%, PGA₂ 0.01%, PGB₂ 0.001%, PGF_{2α} 0.17%, PGD₁ 0.43%, 6keto-PGF_{1α} 0.108%, 15-keto-PGE₂ 0.001%, and arachidonic acid 0.001%. The cross-reactivity of the 6-keto-PGF1a antibody was TxB2, PGE2, and arachidonic acid <0.03%; PGA2 1.8%; PGE1 1.5%; and PGF2a 1.2%.13 The least detectable concentration of the 6keto-PGF_{1α} assay was 12.5 pg and that of the TxB₂ assay was 6.3 pg.

Data were statistically analyzed by one-way analysis of variance and Tukey's test. A p value of <0.05 was considered to be significant.

Results

The serum concentrations of vitamin E and lipid peroxides throughout gestation are shown in Fig. 1. Vitamin E levels were significantly increased in the first trimester of pregnancy as compared with nonpregnancy (5.82 \pm 0.15 vs 5.18 \pm 0.09 μ g/ml, respectively, mean \pm SE, p < 0.01), and they progressively and significantly (p < 0.01) increased throughout the rest of gestation to $8.02 \pm 0.36 \,\mu\text{g/ml}$ at term. The levels of lipid peroxides were significantly increased in the first trimester of pregnancy as compared with nonpregnancy $(3.36 \pm 0.07 \text{ vs } 2.41 \pm 0.02 \text{ nmol/ml, respec-}$ tively, p < 0.01), and they remained significantly elevated throughout the remainder of gestation $(3.45 \pm 0.09 \text{ nmol/ml at term})$. The bottom graph of Fig. 1 shows the change in the ratio of vitamin E to lipid peroxides, which progressively increased throughout pregnancy.

The plasma concentrations of 6-keto-PGF_{1a} and TxB₂ throughout gestation are shown in Fig. 2. The level of 6-keto-PGF1a was significantly less in the first trimester of pregnancy as compared with that of nonpregnancy $(115 \pm 3 \text{ vs } 162 \pm 2 \text{ pg/ml, respectively, } p < 0.01)$, but the concentrations then increased progressively throughout the rest of gestation to 169 ± 8 pg/ml (p < 0.01). The plasma level of TxB₂ was significantly higher in the first trimester of pregnancy than in nonpregnancy (154 \pm 6 vs 102 \pm 2 pg/ml, p < 0.01). The level increased further in the early part of the second trimester (169 \pm 7 pg/ml at 12 to 16 weeks), but then levels progressively decreased during the rest of gestation (106 \pm 6 pg/ml at term, p < 0.01).

The ratio of 6-keto-PGF_{1a} to TxB₂ throughout gestation is shown at the bottom of Fig. 2. The ratio in-

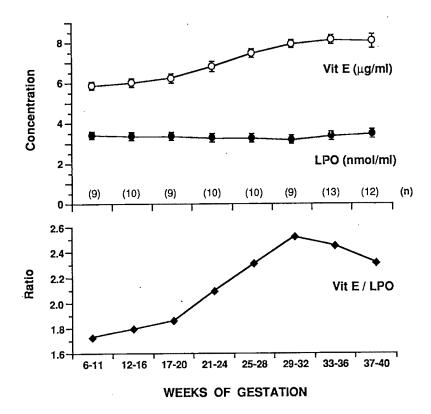

Fig. 1. Top, Maternal serum concentrations of vitamin $E(Vit\,E)$ and lipid peroxides (LPO) throughout gestation in normally pregnant women. Data represent mean \pm SE. Bottom, Ratios of mean concentrations of vitamin E to lipid peroxides throughout gestation.

creased progressively with advancing pregnancy. This increase was highly correlated with the increase in the ratio of vitamin E to lipid peroxides. The correlation coefficient was r = 0.94.

Comment

Our study is the first report of simultaneous measurements of vitamin E, lipid peroxides, 6-keto-PGF_{1α}, and TxB₂ throughout gestation and the first in which samples were collected at frequent intervals. This approach allowed us to assess not only the changes in concentrations of these compounds but also the changes in the ratios of 6-keto-PGF_{1α} to TxB₂ and of vitamin E to lipid peroxides throughout normal pregnancy. We considered the ratios to be important because of the opposing biologic actions of prostacyclin and thromboxane and of vitamin E and lipid peroxides and because imbalances in their ratios favoring the actions of thromboxane and lipid peroxides have been implicated in pathologic pregnancies, such as preeclampsia.

Maternal levels of vitamin E and lipid peroxides were both increased in pregnancy compared with nonpregnancy, which is consistent with previous reports. 14-17 This indicates that both peroxidation and antioxidation reactions are enhanced during pregnancy. The pro-

gressive increase in vitamin E levels throughout the remainder of gestation suggests there is a gradual favoring of antioxidant activity over peroxidation with advancing gestation. This also appears to be true for the placenta, in which concentrations of the antioxidants superoxide dismutase and catalase increase as gestation progresses but lipid peroxide concentrations decrease. 18, 19

The reasons for increased vitamin E levels during pregnancy are not known. Levels may increase as a physiologic response to pregnancy. For example, increased vasodilation may result in increased absorption of vitamin E from the gut. Another explanation is that vitamin E has the same carrier system in blood as cholesterol and triglycerides, the levels of which are increased during pregnancy, ¹⁶ so there may be increased binding capacity of the blood for vitamin E.

The source of increased lipid peroxides during pregnancy is unknown. Increased levels may be related to the increase in serum lipids, because serum lipids spontaneously autooxidize to form lipid peroxides. Maseki et al.²⁰ demonstrated that as the serum concentrations of total lipids increased during pregnancy, so also did the concentrations of lipid peroxides, so the ratio of lipid peroxides to total lipids did not change. Because the placenta produces lipid peroxides, it is another

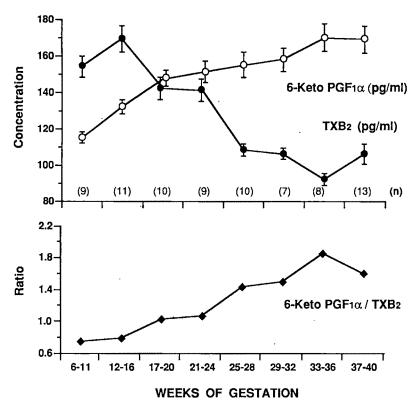

Fig. 2. Top, Maternal plasma concentrations of 6-keto-PGF_{1α} and TxB₂ throughout gestation in normally pregnant women. Data represent mean ± SE. Bottom, Ratios of mean concentrations of 6keto-PGF_{1a} to TxB₂ throughout gestation.

source.18, 19, 21 Placental lipid peroxides apparently contribute to maternal circulating levels because plasma lipid peroxide levels decrease precipitately after delivery.15

6-Keto-PGF_{1a} levels were initially lower in the first trimester than in the nonpregnant state, but then they progressively increased throughout the rest of gestation. This is consistent with reports of other investigators that 6-keto-PGF_{1α} increases with pregnancy, 22-24 although this finding differs with respect to an initial decrease in the first trimester.22,24 Plasma TxB2 levels initially increased in early pregnancy compared with nonpregnancy but then progressively declined with advancing gestation. Some investigators report an increase of TxB2 from early to late pregnancy,25 whereas others report an increase from the first to second trimesters and then a decrease, as we found.24 Previous studies determined either 6-keto-PGF1a or TxB2 concentrations at only two or three stages of pregnancy. Ours is the first study to evaluate the concentration ratios of these substances at frequent intervals throughout gestation.

As pregnancy advanced, the progressive increase in vitamin E levels in relationship to the stable levels of lipid peroxides resulted in a progressive increase in the ratio of vitamin E to lipid peroxides. Similarly, the progressive increase in 6-keto-PGF $_{\scriptscriptstyle 1\alpha}$ concentrations with

advancing gestation, along with the progressive decrease in TxB2 concentrations, resulted in a progressive increase in the ratio of 6-keto-PGF_{1a} to TxB₂. These data indicate that as normal pregnancy advances the concentration ratios progressively favor vitamin E and 6-keto-PGF_{1α}, and they suggest that the antioxidant activity of vitamin E and the vasodilating actions of prostacyclin are progressively favored with advancing gestation. This is not true in pathologic pregnancies, such as preeclampsia, where there is a reversal in these ratios to favor the vasoconstrictive actions of thromboxane and the toxic actions of lipid peroxides.26

IN POSTPARTUM ENDOMETRITIS*

AZACTAM delivers more than you're expecting...

- Broad aerobic gram-negative in vitro coverage, including <u>Escherichia coli</u>, <u>Proteus mirabilis</u>, and <u>Enterobacter cloacae</u>.[†]
- Greater than 90% cure rates in combination with clindamycin.¹⁻³
- No time-consuming, costly, routine therapeutic drug monitoring.
- May be used in penicillin-allergic patients.*
- Pregnancy Category B.

There are no adequate and well-controlled studies in pregnant women. AZACTAM should be used in pregnant women only if clearly needed.

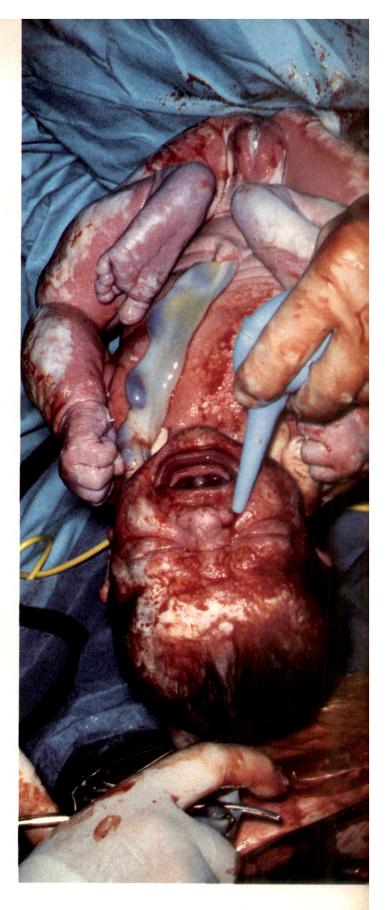

4 randomized, comparative trial of AZACTAM versus gentamicin, each with clindanycin, for the treatment of endometritis after delivery.

Vo universal criteria exist that may satisfy a single definition of "cure." Use of this term nay vary between clinical settings and investigators, and the reader is urged to consult the references listed.

Azactam[®] aztreonam IV/IM 1g/2g

A logical alternative to aminoglycosides.

*Due to susceptible organisms.

†Although a useful guide, in vitro data do not necessarily correlate with therapeutic outcome.

*Antibiotics should be given with caution to any patient who has had some form of allergy, particularly to drugs. See full prescribing information for recommendations on patients with immediate hypersensitivity reactions to penicillins.

Following IV administration, the most commonly seen adverse reactions occurred in less than 2% of patients, including local reactions, diarrhea, nausea/vomiting, and rash

Please see adjacent page for brief summary of prescribing information.

Azactam[®] aztreonam IV/IM 1g/2g

AZACTAM* FOR INJECTION Aztreonam For Injection

DESCRIPTION-AZACTAM (Aztreonam, Squibb) is the first member of a new class of antibiotics classified as monobactams. AZACTAM is a totally synthetic bactericidal antibiotic with activity against a wide spectrum of gram-negative aerobic pathogens. The monobactams, having a unique monocyclic beta-lactam nucleus, are structurally different from other beta-lactam antibiotics.

AZACTAM For Injection is a sterile, nonpyrogenic, sodium-free, white to yellowish-

AZACTAM For Injection is a sterile, nonpyrogenic, sodium-free, white to yellowishwhite lyophilized cake, containing approximately 780 mg arginine per gram of aztreonam for intramuscular or intravenous use following constitution. Aqueous solutions of the product have a pH in the range of 4.5-7.5.

INDICATIONS AND USAGE—Before initiating treatment with AZACTAM, appropriate specimens should be obtained for isolation of the causative organism(s) and for determination of susceptibility to aztreonam. Treatment with AZACTAM may be started empirically before results of the susceptibility testing are available; subsequently, appropriate antibiotic therapy should be continued.

AZACTAM For Injection is indicated for the treatment of the following infections caused by susceptible gram-negative microorganisms: Urlnary Tract Infections (complicated and uncomplicated), including pyelonephritis and cystitis (initial and recurrent) caused by Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa, Enterobacter cloacae, Klebsiella oxytoca*, Citrobacter species* and Serratia marcescens*. Lower Respiratory Tract Infections, including pneumonia and bronchitis caused by Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Haemophilus influenzae, Proteus mirabilis, Enterobacter species and Serratia marcescens*. Septicemia caused by Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa, Proteus mirabilis*, Serratia marcescens* and Enterobacter species Skin and Skin-Structure Infections, including those associated with postoperative wounds, ulcers and burns caused by Escherichia coli, Proteus mirabilis, Serratia marcescens, Enterobacter species, Pseudomonas aeruginosa, Klebsiella pneumoniae, and Citrobacter species* intra-abdominal Infections, including peritonitis caused by Escherichia coli, Klebsiella species, including K. pneumoniae, Enterobacter species including E. cloacae*, Pseudomonas aeruginosa, Citrobacter species* including C. freundii* and Serratia species* including S. marcescens*. Gynecologic Infections, including endometritis and pelvic cellulitis caused by Escherichia coli, Klebsiella pneumoniae*, Enterobacter species* including E. cloacae* and Proteus mirabilis*.

AZACTAM is indicated for adjunctive therapy to surgery in the management of infections including appreciasion including and processor including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion including appreciasion

AZACTAM is indicated for adjunctive therapy to surgery in the management of infections caused by susceptible organisms, including abscesses, infections complicating hollow viscus perforations, cutaneous infections and infections of serous surfaces. AZACTAM is effective against most of the commonly encountered gramnegative aerobic pathogens seen in general surgery.

Concurrent Therapy—Concurrent initial therapy with other antimicrobial agents and AZACTAM is recommended before the causative organism(s) is known in seriously ill patients who are also at risk of having an infection due to gram-positive aerobic pathogens. If anaerobic organisms are also suspected, therapy should be initiated using an anti-anaerobic agent concurrently with AZACTAM. Certain antibiotics (e.g., cefoxitin, imipenem) may induce high levels of beta-lactamase in vitro in some gram-negative aerobes such as Enterobacter and Pseudomonas species, resulting in antagonism to many beta-lactam antibiotics including aztreonam. These in vitro findings suggest that such beta-lactamase inducing antibiotics not be used concurrently with aztreonam. Following identification and susceptibility testing, appropriate antibiotic therapy should be continued.

CONTRAINDICATIONS-Aztreonam is contraindicated in patients with known allergy to this antibiotic

WARNINGS-Pseudomembranous colitis has been reported with nearly all antibacterial agents, including aztreonam, and may range in severity from mild to life threatening. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by Clostridium difficile is one primary cause of "antibiotic-associated colitis."

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to drug discontinuation alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an oral antibacterial drug effective against *C. difficile* (e.g., vancomycin).

*Efficacy for this organism in this organ system was studied in fewer than ten infections.

Careful inquiry should be made for a history of hypersensitivity reaction to any antibiotic or other drugs. Antibiotics should be given with caution to any patient who has had some form of allergy, particularly to drugs. It is recommended that patients who have had immediate hypersensitivity reactions (e.g., anaphylactic or urticarial) to penicillins and/or cephalosporins should be followed with special care. If an allergic reaction to aztreonam occurs, discontinue the drug and institute supportive treatment as appropriate (e.g., maintenance of ventilation, pressor amines, antihistamines, corticosteroids). Serious hypersensitivity reactions may require epinephrine and other emergency measures.

PRECAUTIONS—General: In patients with impaired hepatic or renal function, appropriate monitoring is recommended during therapy. If an aminoglycoside is used concurrently with aztreonam, especially if high dosages of the former are used or therapy is prolonged, renal function should be monitored because of the potential nephrotoxicity and ototoxicity of aminoglycoside antibiotics. The use of antibiotics may promote the overgrowth of nonsusceptible organisms, including gram-positive organisms and fungi. Should superinfection occur during therapy, appropriate measures should be taken.

Carcinogenesis, Mutagenesis, Impairment of Fertility—Carcinogenicity studies in animals have not been performed. Genetic toxicology studies performed in vivo and in vitro with aztreonam in several standard laboratory models revealed no evidence of mutagenic potential at the chromosomal or gene level. Two-generation reproduction studies in rats at daily doses up to 20 times the maximum recommended human dose, prior to and during gestation and lactation, revealed no evidence of impaired fertility. There was a slightly reduced survival rate during the lactation period in the offspring of rats that received the highest dosage, but not in offspring of rats that received five times the maximum recommended human dose.

Pregnancy-Pregnancy Category B: Aztreonam crosses the placenta and enters the fetal circulation. Studies in pregnant rats and rabbits, with daily doses up to 15 and 5 times, respectively, the maximum recommended human dose, revealed no evidence of embryo- or fetotoxicity or teratogenicity. No drug induced changes were seen in any of the maternal, fetal or neonatal parameters that were monitored in rats receiving 15 times the maximum recommended human dose of aztreonam during late gestation and lactation. There are no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, aztreonam should be used during pregnancy only if clearly needed.

Nursing Mothers—Aztreonam is excreted in breast milk in concentrations that are less than 1% of concentrations determined in simultaneously obtained maternal serum; consideration should be given to temporary discontinuation of nursing and use of formula feedings.

Pediatric Use-Safety and effectiveness have not been established in infants and children.

ADVERSE REACTIONS—Local reactions such as phlebitis/thrombophlebitis following IV administration, and discomfort/swelling at the injection site following IM administration occurred at rates of approximately 1.9% and 2.4%, respectively. Systemic reactions (considered to be related to therapy or of uncertain etiology) occurring at an incidence of 1 to 1.3% include diarrhea, nausea and/or vomiting, and rash. Reactions occurring at an incidence of less than 1% are listed within each body system in order of decreasing severity: *Hypersensitivity—anaphylaxis*, angioedema, bronchospasm. *Hematologic—pancytopenia*, neutropenia, thrombocytopenia, anemia, leukocytosis, thrombocytosis. *Gastrointestinal—abdominal cramps; rare cases of *C. difficile-associated diarrhea, including pseudomembranous colitis symptoms may occur during or after antibiotic treatment (see WARNINGS). *Dermatologic—purpura*, erythema multiforme, urticaria, exfoliative dermatitis, petechiae, pruritus, diaphoresis. *Cardiovascular—hypotension, transient ECG changes (ventricular bigeminy and PVC). *Respiratory—one patient experienced flushing, chest pain, and dyspnea. *Hepatobililary—hepatitis, jaundice. *Nervous System—seizure, confusion, vertigo, paresthesia, insomnia, dizziness. *Musculoskeletal—muscular aches. *Special Senses—tinnitus, diplopia, mouth ulcer, altered taste, numb tongue, sneezing and nasal congestion, halitosis. *Other—vaginal candidiasis, vaginitis, breast tenderness. *Body as a Whole—weakness, headache, fever. *malaise.*

Adverse Laboratory Changes—Those reported without regard to drug relationship during clinical trials were: *Hepatic*—elevations of AST (SGOT), ALT (SGPT), and alkaline phosphatase; signs or symptoms of hepatobiliary dysfunction occurred in less than 1% of recipients (see above). *Hemic*—increases in prothrombin and partial thromboplastin times, eosinophilia, positive Coombs test. *Renal*—increases in serum creatinine.

OVERDOSAGE—If necessary, aztreonam may be cleared from the serum by hemodialysis and/or peritoneal dialysis.

DOSAGE AND ADMINISTRATION-Desage adjustments are recommended for patients with impaired renal function. In elderly patients, estimates of creatinine clearance should be obtained and appropriate dosage modifications made if necessary.

HOW SUPPLIED-AZACTAM For Injection (Aztreonam For Injection)-Lyophilized-is supplied in single-dose 15 mL viais containing 500 mg, or 1 g/viai; in single-dose 30 mL viais containing 2 g/viai; and in single-dose 100 mL intravenous infusion bottles containing 500 mg or 1 g or 2 g/bottle.

Consult package insert before prescribing AZACTAM (aztreonam). (J4-231E)

A new era in the field of maternal-fetal medicine has arrived.

MEDICINE OF THE

E. Albert Reece, MD John C. Hobbins, MD Maurice J. Mahoney, MD Roy H. Petrie, MD, ScD With 121 Contributors

A landmark event—the FIRST book to give equal consideration to the fetus and mother

Medicine of the Fetus & Mother is the first comprehensive text to focus on maternal and fetal medicine from the time of conception through early infancy ...including normal processes and disease states of the fetus, the diagnostic and therapeutic measures that can be utilized, and all maternal medical complications of pregnancy.

Clinical and technological advances are transforming maternal-fetal medicine into fetal medicine and maternal medicine.

It is no longer sufficient to treat only the medical complications of the mother during pregnancy. The normal and disease processes of both the fetus and the mother must be treated.

Today's most effective techniques

In 93 chapters, 112 distinguished contributors discuss the complexities of this rapidly evolving and expanding field including..

- reproductive genetics
- invasive diagnostic procedures
- prenatal diagnosis and management of congenital disorders
- fetus at surgery
- in utero cardiac therapy
- fetal metabolic and gene therapy

And, a separate volume of almost 2,000 questions and answers corresponding to chapters in the book provides an exceptional tool for students of medicine reviewing for board examinations.

About 1,488 Pages.

We Have The Technology To Keep You There.

In offices, clinics and hospitals worldwide, Siemens Quantum is changing the way doctors look at their patients.

Our imaging systems and state-of-the-art diagnostics are pushing the limits of ultrasound. Providing more and better information at every level. Performing more types of obstetric and gynecologic studies than ever before.

The Siemens Quantum alliance joins two powerful forces: Siemens, the world's largest medical imaging company, and Quantum, a pioneer and technological leader in ultrasound.

Together, we're committed to maintaining our leading edge. Which means keeping our systems—and our customers—at the forefront of diagnostic imaging.

The Siemens SONOLINE* SI-200 & 250 are versatile, affordable, compact and easy to use.

And they come with the most advanced, multi-frequency, patient-friendly endovaginal probe on the market.

The Siemens SONOLINE* SI-450 offers superb image quality and a comprehensive set of reports and measurement packages. For complete transabdominal, endovaginal and spectral Doppler capabilities, there's no better equipment for the price.

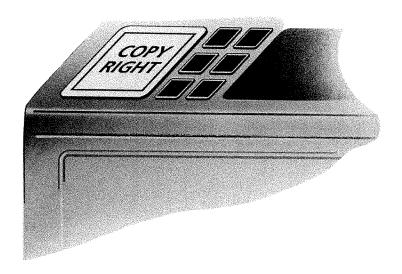

The Quantum 2000 is a high-performance, high-end, all-purpose system that's unsurpassed for high-definition gray scale and ultra-sensitive color flow. Its advanced technology lets you see subtle differences in tissue, accurately image the tiniest flows, and detect even the smallest details at depth.

To receive more information on Siemens Quantum ultrasound systems, call 1-800-367-3569, fax (206) 391-9161, or

> write us at 1040 12th Ave. N.W., Issaquah, WA 98027.

THE OCTO
STAY WITH IT
STAY WITH IT

Simple, easy-to-use Day 1 Start

Patient acceptance proven over time

* Serious as well as minor adverse reactions have been reported following the use of all oral contraceptives. See prescribing information.

See brief summary on adjacent page.

Worldwide Leadership WYETH-AYERST IN Female Healthcare W Philadelphia.PA 19101

THE OC TO START WITH BECAUSE SHE'LL STAY WITH IT

IN BRIEF:
TRIPHASIL* — 6 brown tablets containing 0.050 mg levonorgestrel with 0.030 mg ethinyl estradiol; 5 white tablets containing 0.075 mg levonorgestrel with 0.040 mg ethinyl estradiol; 10 light-yellow tablets containing 0.125 mg levonorgestrel with 0.030 mg ethinyl estradiol; 11 light-green tablets containing inert ingredients are included in the 28-day regimen) — Triphasic regimen.

Indications and Usage — TRIPHASIL* is indicated for the prevention of pregnancy in women who elect to use oral contraceptives (OCs) as a method of contraception.

Contraindications — OCs should not be used in women with any of the following: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep-vein thrombophlebitis or thromboembolic disorders. 3. Cerebral-vascular or coronary-artery disease. 4. Known or suspected carcinoma of the breast. 5. Endometrial carcinoma or other known or suspected strogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

Warnings

Cigarette smoking increases the risk of serious cardiovascular side effects from oral-contra-ceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

should be strongly advised not to smoke.

Use of OCs is associated with increased risks of serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, gallbladder disease, and hypertension, although risk of serious morbidity/mortality is very small in healthy women without underlying risk factors. Morbidity/mortality risk increases significantly if other risk factors present (i.e. hypertension, hyperlipidemias, obesity, diabetes). Practitioners prescribing OCs should be familiar with the following information relating to these risks. (This information is based principally on data irvolving OCs with higher doses of estrogen and progestogen than those commonly used today. Effect of long-term use of lower estrogen and progestogen formulations is yet to be determined.)

1. Thromboembolic Disorders and Other Vascular Problems— MYOCARDIA, INFARCTION (M), An increased risk of MI has been attributed to OC use. Risk is primarily in smokers or women with other underlying risk factors for coronary-artery diseases (i.e. hypertension, hypercholesterolemia, morbid obesity, diabetes). Relative risk of heart attack for current OC users is estimated to be two to six, risk is very low under the age of 30. Smoking combined with OC use contributes substantially to incidence of Mis in women in their mid-thirties or older with smoking accounting for majority of excess cases. Mortality rates associated with circulatory disease increase substantially in smokers over the age of 35 and nonsmokers over the age of 40 among OC users. OCs may compound effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity in particular, some progestogens decrease HDL cholesterol and cause glucose intellerance, while estrogens may create a state of hyperinsulinism. OCs have been shown to increase blood pressure among users (see Warnings). Similar effects on risk factors are associated with increased risk of heart disease. Use OCs with caution in women with cardiovascular diseas

(see Warnings). Similar effects on risk factors are associated with increased risk of heart disease. Use OCs with caution in women with cardiovascular disease risk factors.
THROMBOEMBOLISM. Increased risk of thromboembolic and thrombotic disease associated with OC use is well established. In case control studies relative risk of users compared to non-users was 3 for first episode of superficial venous thrombosis, 4 to 11 for deep-vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. In cohort studies relative risk was somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. Thromboembolic disease risk due to OCs is not related to length of use and disappears after pill use is stopped.

A 2- to 4-fold increase in relative risk of postoperative thromboembolic complications has been reported with OCs. Relative risk of venous thrombosis in women with predisposing conditions is twice that of women without such conditions. If feasible, discontinue OCs at least 4 weeks prior to and for 2 weeks after elective surgery of a type associated with increased risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is associated with an increased thromboembolic risk, start OCs no earlier than 4 to 6 weeks after delivery in women not breast-feeding, or a mild-timester prognancy termination. CEREBROVASCULAR DISEASES. OCs increase relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), in general, risk is greatest among older (> 35 years). Hypertensive women who smoke, hypertensive women who smoke, hypertensive showing interacts to increase hemorrhagic stroke risk.

DOSE-RELATED RISK OF VASCULAR DISEASE FROM OCS. A positive association has been observed between amount of estrogen and progestogen in OCs and vascular disease risk. A decline in serum high density lipoproteins (HDL) is reported with many progestational agents. Seru

The dosage regimen prescribed should contain the least amount of estrogen and progestogen compatible with a low failure rate and individual patient needs. Start new acceptors on preparations containing less than 50 mcg of

estrogen.

PERSISTENCE OF RISK OF VASCULAR DISEASE. Two studies have shown persistence of vascular disease risk for ever-users of OCs. In a U.S. study, MI risk after OC discontinuation persists for at least 9 years in women 40-49 years who had used OCs for five or more years, increased risk was not demonstrated in other age groups. In a study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after OCs stopped, although excess risk was very small. Both studies used OC formulations with 50 micrograms or higher

stopped, aithough excess risk was very small. Both studies used OC formulations with 50 micrograms or higher of estrogens.

2. Estimates of Mortality from Contraceptive Use — A study using data from several sources concluded that with the exception of OC users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is less than that associated with childbirth. The possibility of increased mortality risk with age for OC users is based on data from the 1970s — but reported in 1983. However, current practice involves use of lower estrogen dose formulations combined with careful restriction of OC use to women without the various risk factors listed in this labeling.

Changes in practice and new data suggesting that cardiovascular disease risk with OCs may be less than previously observed prompted the Fertility and Maternal Health Drugs Advisory Committee to review the topic in 1989. The Committee concluded that although cardiovascular-disease risks may be increased with OC use after age 40 in healthy nonsmokers (even with newer low-dose formulations), greater potential health risks are associated with prepancy in older women and with the alternative surgical and medical procedures which may be necessary if effective, acceptable contraception is not available.

The Committee concluded that the benefits of OC use by healthy nonsmoking women over 40 may outweigh the possible risks. Older women, as all women who take OCs, should use the lowest possible effective dose formulation.

formulation.

3. Carcinoma of the Reproductive Organs — Numerous epidemiological studies have looked at the incidence of breast, endometrial, ovarian and cervical cancer in women using OCs. Overwhelming evidence suggests that OC use is not associated with an increase in risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on breast cancer risk for at least a decade following long-term use. A few studies show a slightly increased relative risk of developing breast cancer, although the methodology of these studies show a slightly increased relative risk of developing breast cancer, although the methodology of these studies. Including differences in examination of users and nonusers, and in age at start of use, has been questioned. Some studies suggest that OC use is associated with an increased risk of cervical intraepithelial neoplasia in some populations of women. However, controversy continues about the extent to which such findings may be due to differences in sexual behavior and other factors.

In spite of many studies of the relationship between OC use and breast and cervical cancers, a cause and effect relationship has not been established.

relationshin has not been established

relationship has the overtestablished.

4. Hepatic Neoplasia—Benign hepatic adenomas are associated with OC use, although incidence is rare in the U.S. Indirect calculations estimate attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through introduced in the production of the intra-abdominal hemorrhage

British studies have shown an increased risk of hepatocellular carcinoma in long-term (> 8 years) OC users; these cancers are extremely rare in the U.S. and attributable risk (excess incidence) of liver cancers in OC users approaches less than one per million users.

5. Ocular Lesions — There are clinical case reports of retinal thrombosis with OC use. Discontinue OCs if there is unexplained partial or complete loss of vision, onset of proptosis or diplopia, papilledema, or retinal vascular

is unexplained partial or complete loss of vision, onset of proptosis or diplopia, papilledema, or retinal vascular lesions; undertake appropriate diagnostic and therapeutic measures immediately.

6 Oral-Contraceptive Use Before or During Early Pregnancy — Extensive epidemiological studies revealed no increased risk of birth defects when DCs used prior to pregnancy. Studies do not suggest a teratogenic effect, particularly insofar as cardiac anomalies and limb reduction deflects are concerned, when taken inadvertently during early pregnancy. OC-induced withdrawal bleeding should not be used as a pregnancy test. Do not use Ocs during pregnancy to treat threatened or habitural abortion. Rule out pregnancy of two consecutive periods missed before continuing OC use. If patient has not adhered to prescribed schedule, consider pregnancy at time of first missed period. Discontinue OC if pregnancy confirmed.

7. Gallbladder Disease — Earlier studies reported an increased lifetime relative risk of gallbladder surgery in users of OCs and estrogens, more recent studies show that the relative risk of developing gallbladder disease among OC users may be minimal, which may be related to use of formulations with lower hormonal estrogen and propestogen doses.

progestogen doses.

Indigential states of the state

agents), observe pictalactic and adoctor women cooledney white taking 60s. In hori dataset women, of no apparent effect on fasting blood glucose. A small proportion of women will have persistent hypertriglyceridemia while on OCs. Changes in serum triglycerides and lipoprotein levels have been reported in OC users (see Warnings).

triglycerides and lipoprotein levels have been reported in OC users (see Warnings).

9. Elevated Blood Pressure — Increase in blood pressure has been reported in women on OCs; increase is more likely in older OC users and with continued use. Data show that incidence of hypertension increases with increasing quantities of progestogens.

Encourage women with history of hypertension or hypertension-related diseases, or renal disease to use another contraceptive method. Monitor hypertensive women electing to use OCs closely; discontinue OC if significant blood pressure elevation occurs. For most women elevated blood pressure returns to normal after OC stopped. No difference in occurrence of hypertension among ever- and never-users exists.

10. Headache — Discontinue OC and evaluate cause at onset or exacerbation of migraine, or if new pattern of headache in recurrent presiphent exercises.

10. Headache.— Discontinue OC and evaluate cause at onset or exacerbation of migraine, or if new pattern of headache (i.e. recurrent, persistent, severe) develops.

11. Bleeding Irregularities — Breakthrough bleeding and spotting sometimes occur especially during first 3 months of use. Type and dose of progestogen may be important. Consider non-hormonal causes and take adequate diagnostic measures to rule out malignancy or pregnancy in event of breakthrough bleeding, as with any abnormal vaginal bleeding, if pathylogy excluded, time or a formulation change may solve the problem, in the event of amenorrhea, rule out pregnancy. Some women encounter post-pill amenorrhea or oligomenorrhea especially when such a condition was pre-existent.

Pre-existens.

Precautions

Precautions

1. Physical Examination and Follow Up — A complete medical history and physical examination should be taken prior to initiation or reinstitution of OCs and at least annually during use. Physical exams should include special reference to blood pressure breasts, abdomen and pelvic organs, including cervical cytology, and relevant abnoratory tests. In case of undiagnosed, persistent or recurrent abnormal vaginal bleeding, conduct appropriate diagnostic measures to rule out malignancy. Monitor women with strong family history of breast cancer or who have breast nodules with particular care. 2 Light Disorders.—Follow women being treated for hyperilipidemias closely if they elect to use OCs. Some progestogens may elevate LDL levels and may render control of hyperilipidemias more difficult. See Warningsi 3. Liver Function.—Discontinue OC if Jaundice develops. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. Fluid Retention.—OCs may cause some degree of fluid retention. Prescribe with caution, and only with careful monitoring, in patients with conditions possibly aggravated by fluid retention 5. Emoland Disorders.—It significant depression occurs stop medication and use afternate contraceptive method in attempts to determine if symptom is drug related. Observe carefully those with history of depression and stop drug if depression recurs to serious degree. 6. Contact Lenses—Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. Drug Interactions—Reduced efficacy and increased incidence of breakthrough bleeding and menstrail rregularities are associated with concomitant rifampin use. A similar association, though less marked, is suggested with barbiturates, phenylbutazone, phenyton sodium, and possibly with giseofluvin, amplicillin and tetracyclines. 8. Interactions with Laboratory Tests—Certain endocrine- and liver-function tests and blood components may be affected by OCs. a Increased prothombin and fa

compretely weared.

Information for the Patient — See Patient Package Labeling.

Adverse Reactions — An increased risk of the following serious adverse reactions has been associated with OC use (see Warnings): thrombophlebitis; arterial thromboembolism; pulmonary embolism; myocardial infarction; cerebral hemorrhage; cerebral thrombosis; hypertension; galloladder disease; hepatic adenomas or benign

There is evidence of an association between the following conditions and OC use, although additiona confirmatory studies are needed: mesenteric thrombosis; retinal thrombosis.

confirmatory studies are needed: mesenteric thrombosis; retinal thrombosis. The following adverse reactions have been reported in patients on OCs and are believed to be drug-related nausea, vomiting, gastrointestinal symptoms (such as addominal cramps and bloating); breakthrough bleeding; spotting; change in menstrual flow; amenorhea; temporary intertifity after treatment discontinued; edema; melasma which may persist, breast changes tenderness, enlargement, secretion; change in weight (increase or decrease); change in cervical erosion and secretion; diminution in lactation when given immediately postpartum; cholestatic jaundice; migraine; rash (allergic); mental depression; reduced tolerance to carbohydrates; vaginal candidiasis; change in corneal curvature (steepening); intolerance to contact lenses.

The following adverse reactions have been reported in OC users and the association is neither confirmed nor refuted; congenital anomalies; premenstrual syndrome; cataracts, optic neurits; changes in appetite; cystiris-like syndrome; headache; nenvousness; dizziness; hirsuitsm; loss of scalp hair; erythema multiforme; erythema modosum; hemorrhagic eruption; vaginitis; porphyria; impaired renal function; hemorytic uremic syndrome; Budd-Chiari syndrome; ache; changes in libido; cotilits; sickle-cell disease; cerebral-vascular disease with mitral valve prolapse; lugus-like syndromes.

valve prolapse; lupus-like syndromes.

Overdosage — Serious ill effects havenot been reported following acute ingestion of large doses of OCs by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

Noncontraceptive Health Benefits — The following noncontraceptive health benefits related to OC use are supported by epidemiological studies that largely utilized OC formulations containing doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol. Effects on menses: increased menstrual cycle regularity, decreased blood loss and decreased incidence of iron-deficiency anemia, decreased incidence of dysmenormea. Effects related to inhibition of ovulation decreased incidence of uncidonal ovarian cysts; decreased incidence of ectopic pregnancies. Effects from long-term use: decreased incidence of other processed incidence of the breast, decreased incidence of user pelvic inflammatory disease, decreased incidence of endometrial cancer, decreased incidence of ovarian cancer. decreased incidence of ovarian cancer.

Dosage and Administration — For maximum contraceptive effectiveness, take TRIPHASIL* (levonorgestrel and ethinyl estradiol tablets — triphasic regimen 21- and 28-day regimens) exactly as directed and at intervals not over 24 hours.

If TRIPHASIL® is first taken later than first day of first menstrual cycle of medication or postpartum, contra-ceptive reliance should not be placed on it until after the first 7 consecutive days of use. Possibility of ovulation and conception prior to initiation of medication should be considered.) For full details on dosage and administration see prescribing information in package insert.

The imbalance between thromboxane and prostacyclin in preeclampsia is associated with an imbalance between lipid peroxides and vitamin E in maternal blood

Yuping Wang, MD, a. b Scott W. Walsh, PhD, a Jingde Guo, MD, and Junyan Zhang, MD Richmond, Virginia, and Harbin, People's Republic of China

Preeclampsia is associated with an imbalance between thromboxane and prostacyclin. The cause of the imbalance is unknown. Preeclampsia sera contain cytotoxic factors that can damage endothelial cells. Lipid peroxides can damage cell membranes, so elevated levels in the mother's blood could be related to endothelial cell injury and decreased prostacyclin in preeclampsia. This study determined maternal plasma levels of thromboxane and prostacyclin and serum levels of lipid peroxides and vitamin E in women with normal pregnancy (n = 12), mild preeclampsia (n = 16), and severe preeclampsia (n = 19) between 36 and 40 weeks' gestation. In normal pregnancy the ratio of thromboxane to prostacyclin (0.63) favored prostacyclin, and the ratio of lipid peroxides to vitamin E (0.43) favored vitamin E. Prostacyclin was significantly decreased in both mild and severe preeclampsia: Thromboxane was not increased in mild preeclampsia but was significantly increased in severe preeclampsia. The ratio of thromboxane to prostacyclin was increased in mild preeclampsia (0.77) and greatly increased in severe preeclampsia (1.94). Lipid peroxides were significantly increased in mild preeclampsia and increased further in severe preeclampsia. Vitamin E levels were unaltered in mild preeclampsia but significantly decreased in severe preeclampsia. The ratio of lipid peroxides to vitamin E was increased in mild (0.52) and greatly increased in severe (1.09) preeclampsia. We concluded the following: (1) Maternal plasma prostacyclin is decreased in both mild and severe preeclampsia, but thromboxane is increased only in severe cases. (2) Lipid peroxides are significantly increased in both mild and severe preeclampsia and vitamin E is significantly decreased in severe preeclampsia. We speculate that this imbalance could result in endothelial and platelet cell damage and in decreased prostacyclin and increased thromboxane synthesis. (3) Preeclampsia is associated with an imbalance not only between thromboxane and prostacyclin but also between lipid peroxides and vitamin E in maternal blood. The imbalances progressively favor thromboxane and lipid peroxides with the increasing severity of preeclampsia, which is consistent with the clinical symptoms of this disorder. (AM J OBSTET GYNECOL 1991;165:1695-1700.)

Key words: Lipid peroxides, vitamin E, thromboxane, prostacyclin, preeclampsia

In normal pregnancy the concentration ratio of prostacyclin to thromboxane in maternal blood progressively favors prostacyclin as pregnancy advances, suggesting there is a balance between the actions of prostacyclin and thromboxane that favors the actions of prostacyclin. Prostacyclin is a potent vasodilator, an inhibitor of platelet aggregation, and an inhibitor of uterine contractility, and its combined actions would lead to an increase in uteroplacental blood flow in normal pregnancy. Thromboxane opposes these actions. It is a potent vasoconstrictor, a potent stimulator of platelet

aggregation, and a potent stimulator of uterine contractility, and its combined actions would lead to a decrease in uteroplacental blood flow. In preeclampsia there is an imbalance between thromboxane and prostacyclin that favors the actions of thromboxane.² This imbalance, in itself, can account for the major clinical symptoms of preeclampsia. However, the cause of this imbalance is not known.

In normal pregnancy there is also a change in the concentration ratio of vitamin E to lipid peroxides in maternal blood that progressively favors vitamin E with advancing gestation. Antioxidants are derived from endogenous synthesis or, in the case of vitamin E, from the diet. Antioxidants inhibit peroxidation reactions, and thereby protect enzymes, cells, and proteins from destruction by peroxides. Lipid peroxides are formed when a lipid interacts with a radical, such as the oxygen radical. Lipid peroxides are unstable but highly reactive and very damaging compounds. They stimulate peroxidation reactions and are very toxic to enzymes, cells, and proteins. 4.5

December 1991

1696 Wang et al. Am J Obstet Gynecol

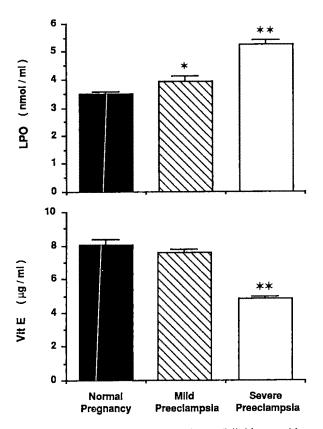

Fig. 1. Maternal serum concentrations of lipid peroxides (LPO) and vitamin E (Vit E) in normal pregnancy and in mild and severe preeclampsia between 36 and 40 weeks of gestation. Data represent mean \pm SE. Asterisk, p < 0.05; two asterisks, p < 0.01 (compared with normal pregnancy).

Rodgers et al.6 reported that preeclampsia sera contain "cytotoxic factors" that damage endothelial cells. The identity of these cytotoxic factors is not known, but lipid peroxides are likely candidates, as suggested by Hubel et al.7 Lipid peroxides enhance blood vessel contractility at doses close to the plasma levels observed in women with preeclampsia,8 and vascular responsiveness to angiotensin II is increased in vitamin E-deficient rats with increased levels of lipid peroxides.9 Even slight increases of lipid peroxides above normal can inhibit enzymes, such as cyclooxygenase and prostacyclin synthase, to decrease prostacyclin synthesis. 10-12 Larger increases damage cell membranes. 4, 5, 12 Damage to the endothelial cells in the kidneys by lipid peroxides might explain proteinuria in preeclampsia.

We hypothesize that in preeclampsia there is an imbalance of increased lipid peroxides and/or decreased antioxidants. We speculate that if there is an imbalance between lipid peroxides and antioxidants, then this imbalance might result in decreased prostacyclin synthesis, endothelial cell injury, and disruption of platelet cell membranes, leading to increased thromboxane production. The purposes of this study were to determine if there is an imbalance between lipid peroxides

and antioxidant activity in preeclampsia and, if such an imbalance exists, to determine if this imbalance is correlated with the imbalance between thromboxane and prostacyclin.

Material and methods

Blood was collected between 36 and 40 weeks' gestation from 12 women with normal pregnancy, 16 with mild preeclampsia, and 19 with severe preeclampsia. Institutional approval was obtained to conduct this study. Mild preeclampsia was defined as a blood pressure of ≥130/90 mm Hg on two separate readings at least 6 hours apart with proteinuria (<2+) or pathologic edema. Severe preeclampsia was defined as a blood pressure of ≥160/110 mm Hg and proteinuria $(\geq 2+)$ with pathologic edema. All subjects were between 20 and 40 years old, and none were taking aspirin or receiving vitamin E therapy.

Venous blood samples (6.0 ml) were collected from the median cubital vein before 9 AM. Two milliliters of each sample was allowed to clot, centrifuged, and used as serum samples for lipid peroxide and vitamin E analysis. Four milliliters of each sample was drawn into a syringe containing 0.2 ml of 2% heparin and 0.05% indomethacin and used as plasma samples for determination of 6-keto-prostaglandin (PG) $F_{l\alpha}$ and thromboxane B₂ (TxB₂) by radioimmunoassay.

Lipid peroxides were estimated by the method of Yagi,13 which measures thiobarbituric acid-reactive products and expresses the data in terms of malondialdehyde. Four milliliters of 1/12N sulfuric acid and 0.5 ml of 10% phosphotungstic acid were added to 20 μl serum and mixed thoroughly. After centrifugation at 3000 rpm for 10 minutes, the liquid phase was decanted. Two milliliters of 1/12N sulfuric acid and 0.3 ml of 10% phosphotungstic acid were added to each sample, mixed, and centrifuged again. The liquid phase was decanted. Four milliliters of double-distilled water and 1.0 ml of TBA reagent (0.67% 2-thiobarbituric acid/acetic acid, 1:1) were then added to each sample, mixed, and heated at 95° C for 1 hour. Samples were cooled with tap water. Five milliliters of n-butyl-alcohol was added, and the samples were vigorously shaken for 1 minute and then centrifuged. The n-butyl-alcohol phase, which contained the lipid peroxides, was used for malondialdehyde analysis with a Shimadzu FR-540 fluorospectrophotometer (Kyoto) with excitation at 515 nm and emission at 553 nm. Tetramethoxy propane (TCI, Tokyo Kasei, Japan) was used as standard and double-distilled water as control. Recovery of exogenously added standard was 98%, and the coefficient of variation for the assay was 6.5%. Assay of varying sample volumes resulted in linear responses parallel to the standard curve.

Vitamin E was determined by fluorometric measure-

Table I. Mean ratios of thromboxane to prostacyclin and lipid peroxides to vitamin E

	Thromboxane/ prostacyclin	Lipid peroxides/ vitamin E
Normal pregnancy	0.63	0.43
Mild preeclampsia	0.77	0.52
Severe preeclampsia	1.94	1.09

ment of tocopherol in serum as described by Abe and Katsui.¹⁴ One milliliter of double-distilled water and 1.0 ml of ethanol were added to 0.2 ml of serum and mixed thoroughly. Five milliliters of n-hexane was added and the samples vigorously shaken for 1 minute. Samples were centrifuged at 1000 rpm for 5 minutes, and the hexane phase was separated and analyzed for tocopherol with a Shimadzu FR-540 fluorospectrophotometer at an excitation of 295 nm and an emission of 320 nm. DL-α-Tocopherol (E. Merck, Germany) was used as standard and double-distilled water as control. Recovery of exogenously added vitamin E was 95%, and the coefficient of variation for the assay was 5.5%. Assay of varying sample volumes resulted in linear responses parallel to the standard curve.

Prostacyclin and thromboxane concentrations were estimated by specific radioimmunoassays of their stable metabolites, 6-keto-PGF₁₀ and TxB₂, respectively, similar to the methods previously described.2 The assays consisted of competitive binding of radioactive and natural TxB2 or 6-keto-PGF10 to specific antibodies. Dextran-coated charcoal was used to separate the bound from the free fraction. Radioimmunoassay kits were obtained from the Department of Pharmacology, Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences (Beijing). The cross-reactivity of the TxB₂ antibody was PGE₂ <0.5%, PGE₁ 0.08%, PGA₂ 0.01%, PGB₂ 0.001%, PGF_{2α} 0.17%, PGD₁ 0.43%, 6-keto-PGF₁₀ 0.108%, 15-keto-PGE₂ 0.001%, and arachidonic acid 0.001%. The cross-reactivity of the 6-keto-PGF1a antibody was TxB2, PGE2, and arachidonic acid <0.03%, PGA₂ 1.8%, PGE₁ 1.5%, and PGF_{2α} 1.2%.15 The least detectable concentration of the 6-keto-PGF1a assay was 12.5 pg and that of the TxB2 assay was 6.3 pg.

Data were statistically analyzed by one-way analysis of variance and Tukey's test. A p value of <0.05 was considered significant.

Results

The concentrations of lipid peroxides and vitamin E for normal pregnancy (n = 12), mild preeclampsia (n = 16), and severe preeclampsia (n = 19) are shown in Fig. 1. Lipid peroxides were significantly increased in mild preeclampsia (3.94 ± 0.16 nmol/ml, mean \pm SE, p < 0.05) as compared with normal preg-

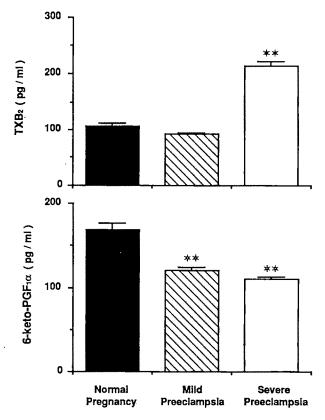

Fig. 2. Maternal plasma concentrations of stable metabolites of thromboxane and prostacyclin, TxB2 and 6-keto-PGF1a, respectively, in normal pregnancy and in mild and severe preeclampsia between 36 and 40 weeks of gestation. Data represent mean \pm SE. Asterisk, p < 0.01, compared with normal pregnancy.

nancy (3.45 ± 0.09 nmol/ml) and increased still further in severe preeclampsia $(5.26 \pm 0.15 \text{ nmol/ml})$, p < 0.01). Vitamin E levels were unaltered in mild preeclampsia (7.55 \pm 0.25 μ g/ml) and significantly decreased in severe preeclampsia (4.83 ± 0.11 μg/ml, p < 0.01) as compared with normal pregnancy $(8.02 \pm 0.36 \,\mu g/ml)$.

The concentrations of TxB2 and 6-keto-PGF1 are shown in Fig. 2. TxB₂ concentrations were not increased in mild preeclampsia (92 ± 2 pg/ml, mean \pm SE, n = 16) as compared with normal pregnancy (106 \pm 6 pg/ml, n = 12), but they were significantly increased in severe preeclampsia (213 ± 8 pg/ml, p < 0.01, n = 19). The concentrations of prostacyclin's stable metabolite, 6-keto-PGF₁₀, were significantly decreased in both mild (120 ± 4 pg/ml, p < 0.01) and severe (110 ± 3 pg/ml, p < 0.01) preeclampsia as compared with normal pregnancy $(169 \pm 8 \text{ pg/ml}).$

Table I compares the mean ratios of thromboxane to prostacyclin with lipid peroxides to vitamin E for normal pregnancy and for mild and severe preeclampsia. Both ratios increased in mild preeclampsia com-

NORMAL PREGNANCY

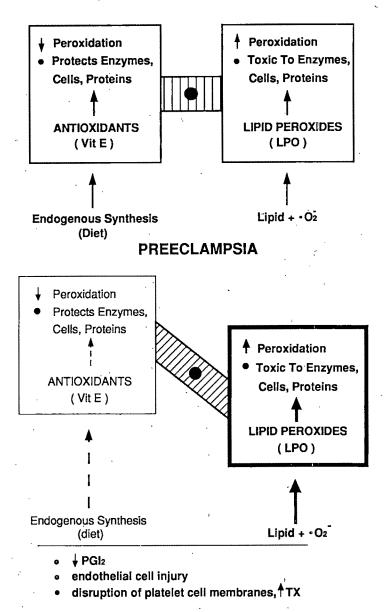

Fig. 3. Comparison of balance in biologic actions of antioxidants and lipid peroxides in normal pregnancy with imbalance of increased lipid peroxides/decreased vitamin E in preeclamptic pregnancy. Boldface type and box for lipid peroxides suggest exacerbation of their actions in preeclampsia, whereas lightface type and box for antioxidants suggest diminution of their actions.

pared with normal pregnancy and increased even further in severe preeclampsia. The relationship of the two ratios was linear (y = -0.29 + 2.04x) and highly correlated with a correlation coefficient of r = 0.997.

Comment

This is the first study to compare thromboxane and prostacyclin levels in mild preeclampsia with levels in severe preeclampsia. Maternal prostacyclin was decreased in both mild and severe preeclampsia as compared with normal pregnancy, but maternal thromboxane was increased only in severe preeclampsia (Fig.

2). The decrease in prostacyclin in preeclampsia is well documented, ¹⁶ but less information is available for thromboxane. Benigni et al. ¹⁷ also found no increase in maternal serum thromboxane levels in women with mild preeclampsia. Placental thromboxane production is significantly increased in mild preeclampsia, ² but placental thromboxane probably contributes little to maternal serum levels. The significant increase in maternal thromboxane levels we found in severe preeclampsia may be related to disruption of platelet cell membranes caused by the significant increase in lipid peroxides.

This study is also the first to compare lipid peroxide

and antioxidant levels in mild preeclampsia with levels in severe preeclampsia. Lipid peroxides were increased slightly, but significantly, in mild preeclampsia and substantially increased in severe preeclampsia as compared with normal pregnancy. Vitamin E levels were unaltered in mild preeclampsia, but markedly decreased in severe preeclampsia (Fig. 1). Other investigators have also found an increase in lipid peroxides in mild and severe preeclampsia 18-20 and a decrease in vitamin E or antioxidant activity20-22 in women with severe preeclampsia, as compared with normal pregnancy. Vitamin E was not decreased in one study of women with mild preeclampsia,23 which is consistent with our findings.

Increased thromboxane and increased lipid peroxides in preeclampsia may be coupled by the cyclooxygenase enzyme, because cyclooxygenase activity generates oxygen radicals24 that can then interact with polyunsaturated fatty acids to form lipid peroxides. Increased placental thromboxane production in preeclampsia2 may be related to the increase in lipid peroxides. The placenta is a rich source of polyunsaturated fatty acids,25 so the combination of increased oxygen radicals generated from thromboxane production with the high placental content of fatty acids would result in increased placental formation of lipid peroxides. One report indicates placental lipid peroxide autooxidation is significantly increased in preeclampsia.26

Decreased prostacyclin and vitamin E levels may be related to the increased levels of lipid peroxides. Even slight increases above normal for lipid peroxides inhibit prostacyclin synthase, and larger increases inhibit cyclooxygenase. 10-12 Thromboxane synthase does not appear to be affected by lipid peroxides.10 Still larger increases in lipid peroxides damage endothelial cell membranes, which could further impair prostacyclin synthesis.

Vitamin E is a free radical scavenger and thus exerts its antioxidant activity. However, vitamin E is consumed in exerting its action, so abnormal increases in lipid peroxides in preeclampsia could increase consumption, resulting in the decreased vitamin E levels. Another possibility is decreased absorption of vitamin E from the gut as a result of the vasoconstriction of preeclampsia.

Combining low-dose aspirin therapy to selectively inhibit thromboxane production with vitamin E supplementation to reduce lipid peroxide levels may be beneficial and further improve clinical outcomes of preeclamptic patients. Several studies indicate the positive effects of low-dose aspirin therapy for the prevention of preeclampsia, as recently reviewed,16 and at least two studies have reported beneficial effects of vitamin E supplementation or antioxidant drug therapy.27,28 Shalina et al.27 reported improvement and elimination of the momentume of areadamness with antioxidant drive therapy, but after withdrawal of the therapy the signs of the disease reappeared within 2 to 6 days.

In summary, preeclampsia is associated with an imbalance not only between thromboxane and prostacyclin but also between lipid peroxides and antioxidant activity. The imbalances are correlated and progressively favor thromboxane and lipid peroxides with the severity of preeclampsia, which is consistent with the clinical symptoms of this disorder. We speculate that the imbalance between lipid peroxides and vitamin E may result in decreased prostacyclin synthesis and endothelial cell injury in mild preeclampsia and, in addition, in disruption of platelet cell membranes leading to increased thromboxane production in severe preeclampsia (Fig. 3).

Antioxidant systems in normal pregnancy and in pregnancy-induced hypertension

Stephen J. Wisdom, MB, ChB,^a Rhoda Wilson, PhD,^b James H. McKillop, PhD,^b and James J. Walker, MB, ChB^a

Glasgow, Scotland

Increased free radical activity has been implicated in the pathogenesis of pregnancy-induced hypertension. This article investigates whether changes in antioxidant systems contribute to this condition. Two extracellular (plasma thiols and ceruloplasmin) and two intracellular (red blood cell lysate thiols and red blood cell superoxide dismutase) antioxidant markers were assayed in 25 nonpregnant women, 16 pregnant women with normal blood pressure, 19 women with pregnancy-induced hypertension, and 13 women with proteinuric pregnancy-induced hypertension. In the normotensive pregnant group (in comparison with the nonpregnant group) the plasma thiol level was reduced (p < 0.001) and the ceruloplasmin level raised (p < 0.005), suggesting increased free radical activity. The lysate thiol level increased (p < 0.005), which may reflect a compensatory protective response. In the hypertensive pregnant groups the lysate thiol rise was not present. These red blood cells may be more prone to oxidative stress. Whether this situation is a cause or an effect of oxidative stress in pregnancy-induced hypertension has yet to be elucidated. (AM J OBSTET GYNECOL 1991;165:1701-4.)

Key words: Antioxidants, free radicals, pregnancy-induced hypertension

Damage from free radicals has been implicated in many pathologic conditions. It is envisaged that increased free radical activity (oxidative stress) arises from increased production of free radicals or a deficiency in the protective antioxidant systems. Pregnancy-induced hypertension is associated with endothelial cell dysfunction. Such dysfunction could be caused by oxidative stress: the unsaturated lipids and thiol-containing proteins in cell membranes are susceptible to free radical attack. There is evidence of increased free radical activity in pregnancy-induced hypertension. but little is known about the part played by changes in specific antioxidants.

In this study two extracellular (plasma thiols and ceruloplasmin) and two intracellular (red blood cell lysate thiols and red blood cell superoxide dismutase) components of antioxidant systems have been assessed to reflect the oxidative stress across the cell membrane.

Thiol groups are involved in the defense against oxidative stress.⁶ Oxidative stress will result in the conversion of thiol groups to disulfide forms, with a consequent fall in the observed thiol level. Plasma thiols are a heterogeneous group offering a nonspecific buffer to oxidative stress. Red blood cell lysate thiols

consist mainly of glutathione, which has a specific antioxidant role.

The exact mechanism for the antioxidant ability of ceruloplasmin is uncertain. It may function by converting Fe²⁺ to Fe³⁺, Fe²⁺ being an autooxidation catalyst.⁷ Superoxide dismutase specifically detoxifies the superoxide anion radical. Because ceruloplasmin and superoxide dismutase have enzymic roles, they are not consumed by oxidative stress. Their levels, however, indicate the capacity to withstand oxidative stress and teleologically would be expected to be elevated in response to oxidative stress.

The effects of pregnancy and pregnancy-induced hypertension on these four antioxidant parameters were investigated.

Material and methods

There were four study groups: healthy, nonpregnant women in the reproductive era (n=25); pregnant women with normal blood pressure (n=16); women with pregnancy-induced hypertension without proteinuria (n=19); and women with pregnancy-induced hypertension with proteinuria (n=13). All pregnant women were primigravid and in the third trimester.

Pregnancy-induced hypertension was defined as a persistent or recurrent diastolic blood pressure of ≥ 90 mm Hg developing during pregnancy at >20 weeks' gestation, and resolving ≤ 6 weeks post partum. Proteinuria was defined as the persistent presence of protein in the urine of $\geq +$ on urine "dipstick" testing or >300 mg of protein excreted in 24 hours (this measurement was preferred where available).

Table I. Antioxidant levels in normotensive pregnant and pregnancy-induced hypertension groups compared with nonpregnant control group

	M	Normotensive pregnant		PIH without proteinuria		PIH with proteinuria	
	Nonpregnant (mean ± SD)	Mean ± SD	p Value	Mean ± SD	p Value	Mean ± SD	p Value
Plasma thiols (U/L)	466 ± 59	292 ± 85	< 0.001	301 ± 96	< 0.001	251 ± 82	< 0.001
Ceruloplasmin (mg/100 ml)	19 ± 11	29 ± 10	< 0.005	27 ± 9	< 0.05	35 ± 8	< 0.00
Lysate thiols (U/L)	288 ± 112	453 ± 197	< 0.005	279 ± 123	NS	313 ± 115	NS
Superoxide dismutase (µg/ml)	62 ± 29	39 ± 15	< 0.005	38 ± 24	< 0.01	29 ± 16	< 0.005

p Values shown where results are of significant difference from the nonpregnant group. PIH, Pregnancy-induced hypertension; NS, not significant.

Each subject had blood sampled on one occasion. The blood was stored at 4° C and assayed within 24 hours. Preliminary studies had shown that the antioxidant levels being measured did not alter during this storage, staying within the intraassay variations (quoted below). The methods for thiol, ceruloplasmin, and superoxide dismutase estimation were described by Banford et al.8.9 Lysate thiol and plasma thiol levels were measured with the thiol-disulfide interchange reaction between 5,5'-dithio-bis(2-nitrobenzoic acid) and biologic thiols.10 Plasma ceruloplasmin activity was measured with a modification of the method of Menden et al.11 on the basis of the ceruloplasmin-catalyzed oxidation of p-phenylenediamine to Bandrowski's base. Superoxide dismutase activity was measured according to the method of Misra and Fridovich¹² on the basis of the increase in the rate of photooxidation of o-dianisidine. The intraassay and interassay variations were, respectively, 1.0% and 7.0% for lysate thiol levels, 1.2% and 1.7% for plasma thiol levels, 3.0% and 10.0% for ceruloplasmin levels, and 4.6% and 7.0% for superoxide dismutase levels.

Coincidental serum urate and blood platelet concentrations were available for the women with hypertension

Statistical significance was assessed by Student's t test.

Results

There were no significant differences in patient ages between the four study groups: nonpregnant, 26.9 ± 4.2 years (mean \pm SD); normotensive pregnant, 24.1 ± 4.0 years; pregnancy-induced hypertension without proteinuria, 24.5 ± 6.0 years; and pregnancy-induced hypertension with proteinuria, 22.2 ± 4.9 years. There were no significant differences in gestational ages between the pregnant groups: normotensive pregnant, 37.0 ± 3.3 weeks; pregnancy-induced hypertension without proteinuria, 37.8 ± 2.7 weeks; pregnancy-induced hypertension with proteinuria, 36.3 ± 3.6 weeks.

The ceruloplasmin and lysate thiol levels in the normotensive pregnant group were significantly higher and the plasma thiol and superoxide dismutase levels significantly lower than those levels in the nonpregnant group (Table I). Similar changes occurred in the hypertensive groups, except that the rise in lysate thiol levels was not found. Hence the lysate thiol levels in the pregnancy-induced hypertension groups with and without proteinuria were lower (p < 0.005 and p < 0.05, respectively) than in the normotensive pregnant group.

The only significant difference between the two hypertensive groups was that the ceruloplasmin level was higher in the pregnancy-induced hypertension with proteinuria group than in the pregnancy-induced hypertension without proteinuria group (p < 0.05).

There was a trend toward higher serum urate levels in the pregnancy-induced hypertension with proteinuria group (342 \pm 31 mmol/L mean \pm SD) in comparison with the pregnancy-induced hypertension without proteinuria group (297 \pm 83 mmol/L), but this increase did not reach significance. Blood platelet concentrations were similar in the pregnancy-induced hypertension without proteinuria (243 \pm 86 \times 10°/L) and pregnancy-induced hypertension with proteinuria (239 \pm 60 \times 10°/L) groups.

Comment

Free radicals, by their unstable and transient nature, are difficult to measure directly. Their tendency to cause lipid peroxidation¹³ has been used as an indirect measure. Markers of lipid peroxidation have been found to rise during the progression of normal pregnancy, with greater rises seen in association with pregnancy-induced hypertension.^{4, 5} Knowledge of the responses of the antioxidant systems in pregnancy and in pregnancy-induced hypertension is limited. Increasing serum antioxidant activity has been documented during normal pregnancy.¹⁴ Plasma proteins and uric acid form major components of crude antioxidant ac-

tivity. These are not dedicated antioxidants, and changes in their levels will reflect factors other than free radical attack.

In this study examination of antioxidant status in pregnancy and pregnancy-induced hypertension has been extended. Intracellular and more specific antioxidant system components have been assayed. The red blood cell was selected because it is easily accessible and may be affected in pregnancy-induced hypertension (e.g., hemolysis). It is rich in thiol functions, which are potentially involved in attack from and protection against free radicals.

Plasma thiol levels were found to be decreased and ceruloplasmin levels increased in the third trimester of normal pregnancy (compared with the nonpregnant group). Such changes are compatible with oxidative stress. The measured fall in plasma thiol concentration was greater than would be expected simply from the normal hemodilutional changes of pregnancy. Ceruloplasmin is an acute phase reactant; a rise in its level occurs with a variety of tissue insults. Thus it is difficult to attribute a cause to the elevated level, although oxidative stress is not precluded from being mechanistically involved.

The lysate thiol level was elevated in normal pregnancy. This elevation suggests either that there was less oxidative stress within the red blood cell or that the red blood cell had been provided with a higher thiol content. Both circumstances indicate that the red blood cell has increased protection against free radical attack from its environment. It is possible that such changes are required to guard the pregnant woman against a scenario of increased free radical production.

In normal pregnancy the superoxide dismutase activity was reduced. The significance of this finding is uncertain. It could reflect reduced enzyme production, implying reduced intracellular oxidative stress, or enzyme inactivation. If the cause of enzyme inactivation is related to the pathogenesis of pregnancy-induced hypertension, the superoxide dismutase activity would be expected to be lower in the hypertensive groups. Although the superoxide dismutase activity was lowest in the pregnancy-induced hypertension with proteinuria group, this low level of activity did not reach significance in comparison with the other pregnant groups. A fall in superoxide dismutase activity has also been recorded with rheumatoid arthritis9 and Graves' disease.15

In the pregnancy-induced hypertension without proteinuria and pregnancy-induced hypertension with proteinuria groups the lysate thiol amounts were significantly lower than those seen in normal pregnancy. It is anticipated that such red blood cells would be more susceptible to oxidative stress. Whether this lower lysate thiol level is a cause or an effect of pregnancy-induced hypertension cannot be concluded from this study.

The ceruloplasmin level was higher (p < 0.05) in the pregnancy-induced hypertension with proteinuria group than in the pregnancy-induced hypertension without proteinuria group. This difference could reflect greater oxidative stress being present in more severe pregnancy-induced hypertension.

It has been postulated that red blood cell dysfunction is fundamental in the development of pregnancyinduced hypertension,16 and we found antioxidant changes in the red blood cell. Similar alterations in the balance of the thiol system could be present across the endothelial cell membrane. The superoxide anion can inactivate endothelium-derived relaxing factor17 and inhibit prostacyclin synthesis.18 Lipid peroxidation products may inhibit prostacyclin synthesis 19 and stimulate smooth-muscle contraction.20 Therefore increased free radical activity may cause platelet aggregation and vasospasm, features of pregnancy-induced hypertension.

The sample sizes in this initial study are small, and the results are susceptible to β -type errors. However, changes in the antioxidant systems in normal pregnancy and in pregnancy-induced hypertension have been demonstrated. In normal pregnancy there is evidence for increased oxidative stress in the plasma compartment, but with raised red blood cell thiol defenses. In pregnancy-induced hypertension these red blood cell defenses are lowered or overcome.

The altered balances of thiol groups across the red blood cell membrane are to be investigated further with in vitro studies of intact red blood cells from subjects with pregnancy-induced hypertension.

Studies in early pregnancy are being performed to establish when the antioxidant changes of normal pregnancy occur, and whether a pattern of predictive pregnancy-induced hypertension exists.

Editors' note

The AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY introduces a new format for abstracts accompanying regular articles, society articles, and Current Investigation articles. Authors submitting these manuscripts to the JOURNAL should provide an abstract of no more than 150 words structured according to the following headings: Objective(s), Study Design, Results, and Conclusion(s). Exceptions to this requirement include Clinical Opinion, Current Development, case report, and brief communication articles. Abstracts for these articles will continue to follow the standard abstract format. Please consult the Information for Authors for details.

Selective effects of preeclamptic sera on human endothelial cell procoagulant protein expression

Robert N. Taylor, MD, PhD, David C. Casal, PhD, Lynn A. Jones, MA, Madhu Varma, PhD, James N. Martin, Jr., MD, and James M. Roberts, MD

San Francisco and Sunnyvale, California, and Jackson, Mississippi

Current concepts of preeclampsia suggest that dysfunction of maternal vascular endothelium in vivo is a central pathogenetic feature of this syndrome. This hypothesis is suggested by the activation of the coagulation cascade associated with preeclampsia and evidence for a role of endothelium in maintaining thromboresistance. Previous in vitro studies with monolayers of human umbilical vein endothelial cells demonstrated direct cytotoxic effects of sera from preeclamptic parturients. In the current studies, we have examined the in vitro expression of three procoagulant protein activities regulated by endothelial cells: cellular fibronectin, an important mediator of platelet aggregation known to be elevated in preeclamptic women in vivo; tissue factor, the most potent endogenous procoagulant activity; and von Willebrand factor, a major component of coagulation factor VIII. Monolayer cultures of human umbilical yein endothelial cells were incubated with pregnancy sera for 24 hours before these proteins and activities were quantified. Exposure of identical endothelial cell cultures to predelivery preeclamptic sera caused significantly greater release of cellular fibronectin than postdelivery preeclamptic or predelivery or postdelivery normal pregnancy sera (p < 0.05). However, neither tissue factor activity nor von Willebrand factor expression appeared to be increased preferentially by preeclamptic sera. The data indicate that sera from women with preeclampsia induce a selective, but not a generalized, activation of endothelial cell procoagulant protein production. (AM J OBSTET GYNECOL 1991;165:1705-10.)

Key words: Preeclampsia, endothelial cell activation, procoagulant

Preeclampsia is a multisystemic, pregnancy-specific disorder defined clinically as a syndrome of elevated blood pressure, excessive proteinuria, and generalized edema.¹ Because of the associated signs of activation of the coagulation cascade and increased sensitivity to vasopressor agents, we have proposed that maternal vascular endothelial cell injury or activation is central to the development of the preeclamptic syndrome.² This hypothesis is supported by recent findings that have elucidated the role of endothelial cells in the balance between anticoagulant and procoagulant activity expression at the vessel wall. The syndrome of disseminated intravascular coagulation is a severe and rare clinical complication of sepsis and preeclampsia. However, local intravascular clotting and occlusion may oc-

cur by subtle forms of immune or inflammatory activation, such as have been proposed in preeclampsia.¹

Previous studies designed to assess the direct effects of preeclamptic sera on human endothelial cells in vitro demonstrated an increase in chromium 51 release,3 a nonspecific indicator of endothelial cell injury, and the stimulation of platelet-derived growth factor synthesis.4 This report describes our examination of the in vitro expression of three regulated procoagulant protein activities in endothelial cells. Cellular fibronectin is an endothelium-derived isoform of fibronectin, a highmolecular-weight extracellular matrix glycoprotein involved in several fundamental cell functions. Of particular relevance to preeclampsia, cellular fibronectin mediates platelet adherence and aggregation at sites of endothelial cell injury.5 Tissue factor, a procoagulant protein synthesized and secreted by endothelial cells, is believed to be the most potent endogenous thrombogenic agent in man.6 von Willebrand factor is an endothelium-derived component of the factor VIII antigen complex, that is known to be deposited in areas of endothelial cell injury, where it mediates platelet adhesion at these sites.7 To test directly the hypothesis that a blood-borne factor(s) in women with preeclampsia modulates endothelial cell procoagulant expression, human endothelial cell monolayers were exposed to matched normal and preeclamptic pregnancy sera in vitro and assayed for altered expression of these throm-

All clinical and laboratory abnormalities must return to normal by 12 weeks post partum.

bogenic proteins. We report that serum obtained from preeclamptic women causes increased cellular fibronectin release from human umbilical endothelial cells in vitro, but effects on tissue factor and von Willebrand factor were not observed.

Material and methods

Pregnant women registering for prenatal care at Moffitt-Long Hospital and San Francisco General Hospital of the University of California, San Francisco and the University of Mississippi Medical Center were invited to participate in a prospective study of preeclampsia. Participating patients gave written consent for blood sampling in the late third trimester and again within 48 hours of delivery, as approved by the universities' committees on human research. Blood samples were collected in sterile tubes, and serum was prepared and frozen at -70° C for later use. For the predelivery specimens blood was collected before intravenous hydration, magnesium sulfate infusion, or antihypertensive medication and thus was unaffected by differences in the clinical management or therapy of parturients believed to have preeclampsia.

The patients selected for this case-control study were monitored throughout pregnancy, including labor and delivery at term (≥36 weeks' gestation) and for 12 weeks post partum with serial clinical observations. At the completion of their final postpartum evaluation, the clinical and laboratory data were reviewed by a jury of clinical investigators. Nulliparous patients were assigned to the preeclamptic study group on the basis of the recommendations of Chesley, as described in Table I. Criteria that resulted in the exclusion of patients from this study were the identification of essential hypertension or other metabolic diseases, evidence of illicit drug use by urine toxicology screens, or the failure of elevated blood pressure or proteinuria to resolve within

12 weeks of delivery. Normal controls were matched as closely as possible for parity, maternal age, and gestational age at delivery to the preeclamptic cases.

Human umbilical vein endothelial cells³ and human renal microvascular endothelial cells4 were harvested and cultured as described previously. Monolayers were grown to confluence with M-199 tissue culture media supplemented with 20% fetal bovine serum on gelatincoated Falcon 24- or 96-well plates (Becton-Dickinson, Lincoln Park, N.J.). The cell cultures were made quiescent'in serum-free M-199 media containing 500 µg/ml bovine serum albumin, 5 µg/ml transferrin, 1 µg/ml insulin, and 2 U/ml heparin for 24 hours before serumfree media containing endotoxin or 10% prepartum or postpartum human pregnancy sera were added. After an additional 24 hours' incubation the cells were assayed for tissue factor activity or von Willebrand factor as described below. Cells from representative wells were trypsinized and counted with a hemocytometer to allow normalization of procoagulant protein concentration or activity on a per cell basis.

Conditioned media were collected, brought to a final concentration of 1% aprotinin, and frozen at -70° C until assays for cellular fibronectin were performed. Cellular fibronectin levels were determined by a specific enzyme-linked immunosorbent assay (ELISA) technique with the monoclonal antibody A134, which recognizes a conformational epitope near the ED-B domain of cellular fibronectin.10 Aliquots of 100 µl of endothelial cell-conditioned medium were thawed at 37° C, diluted 1:2 with sample buffer, and assayed in duplicate. The accumulation of A134 cellular fibronectin in the endothelial cell culture supernatant was linear over 72 hours. Normal term pregnancy plasma contains cellular fibronectin in concentrations ranging from 1 to 9 µg/ml with greater levels found in preeclamptic women (range 2 to 21 µg/ml).10 However, this protein precipitates from serum during clot formation. When the 10% pregnancy serum-containing media were assayed by ELISA, no cellular fibronectin (<0.1 μg/ml) was detected in either normal or preeclampsia serum-reconstituted media. The performance characteristics and specificity of this assay, which was developed and performed at Adeza Biomedical, Sunnyvale, Calif., have been described previously.¹⁰

Tissue factor activity was measured directly in intact cells with a modification of the method of Zuckerman and Suprenant.¹¹ To each well of washed human umbilical vein endothelial cells were added 1 U each of factors VII and X (F-6509 and F-4634, respectively, Sigma Chemical Co., St. Louis). After 15 minutes' incubation at room temperature, a 1 mmol/L solution of the chromogenic substrate S-2222 (Sigma) was added to the cell supernatant, and the reaction was quantified kinetically for 4 minutes at 405 nm using

Shimadzu UV-160 spectrophotometer (Shimadzu Corp., Kyoto).

von Willebrand factor expression was assayed directly on fixed endothelial cells with a whole-cell ELISA technique. Human umbilical vein endothelial cells were exposed to pregnancy serum containing or control media with or without endotoxin for 24 hours, washed gently with M-199 media, and fixed in 2% paraformaldehyde-cacodylate buffer (pH 7.4) for 1 to 2 hours at 4° C. The cells were then washed three times with M-199 containing 5% fetal bovine serum and incubated with rabbit antihuman von Willebrand factor antisera (Dako, Santa Barbara, Calif.) at a 1:3200 dilution, which prior studies revealed to yield an optimal signal/noise ratio at 30 minutes' reaction time. Goat antirabbit immunoglobulin G conjugated to alkaline phosphatase (Vector Labs, Burlingame, Calif., 1:250 dilution) was incubated for 60 minutes and p-nitrophenyl phosphate disodium substrate (0.7 mg/ml, No. S-104, Sigma) was allowed to react for 30 minutes. The final reaction product was quantified with a microplate reader (model 3550, Bio-Rad, Richmond, Calif.) at 405 nm.

For all three assays, exposure of human umbilical vein endothelial cells to serum-free media alone and media containing endotoxin (lipopolysaccharide from Escherichia coli serotype 055:B5, 1 µg/ml, No. L-4005, Sigma) provided negative and positive controls respectively, for endothelial cell activation. Cellular fibronectin concentrations in the conditioned media are expressed as micrograms released per milliliter per 106 cells. Tissue factor activity is expressed as the change in optical density units in milliunits per minute per 106 cells. von Willebrand factor expression is presented as optical density units per 30 minutes per 106 cells. The experimental data are reported as the group mean ± SE. Paired and unpaired Student t tests were used in appropriate experiments, and conservative, nonparametric Mann-Whitney tests were used to compare the two groups of patients. Two-tailed analyses with p < 0.05 were considered significantly different.

Results

Nine women who met the requirements for the diagnosis of preeclampsia (Table I) were matched to nine normal, control parturients. The results in Table II show the mean \pm SE values for each of the clinical and biochemical parameters examined at term. As expected from diagnostic critera, patients defined as having preeclampsia had significantly greater mean arterial blood pressure, proteinuria, and uric acid levels than the normal parturients had (p < 0.05, Mann-Whitney tests); otherwise, the cases and controls were well matched (Table II).

To establish a positive control for the activation of

monolayer cultures of human umbilical vein endothelial cells, we incubated these cells in serum-free medium in the presence of endotoxin (1 µg/ml). Other experiments in our laboratory have demonstrated that "activated" functional and morphologic changes in human umbilical vein endothelial cells can be induced by exposure to endotoxin and interleukin-1β (unpublished observations and as described by others12). By paired analyses 1 µg/ml endotoxin induces significant increases in measurable cellular fibronectin, tissue factor, and von Willebrand factor as compared with matched human umbilical vein endothelial cell cultures without endotoxin treatment (p < 0.01, Table III).¹¹ The expression of cellular fibronectin by cultured adult human renal microvascular endothelial cells4 (1.4 μg/ml/106 cells), grown under similar serum-free conditions for 24 hours, indicates that fibronectin molecules bearing the A134 epitope are not restricted to cells of fetal origin. The specific details of each experiment are described below.

Previous studies of human umbilical vein endothelial cell perturbation had demonstrated that 10% dilutions of pregnancy sera gave reproducible and discriminating effects when normal and preeclamptic samples were compared.^{8, 4} In the experiments decribed in Table III, human umbilical vein endothelial cells were incubated with 10% predelivery and postdelivery sera from the same patients. Conditioned media were re-

Data are presented as mean \pm SE of number of individual experiments (n).

moved from the cell cultures and assayed with cellular fibronectin ELISA described above. Cells exposed to 10% normal predelivery sera released 1.0 \pm 0.1 μg cellular fibronectin per milliliter per 10⁶ cells (mean ± SE, n = 6) into their conditioned media, whereas conditioned media from identical cells treated with 10% normal postdelivery sera contained 1.1 ± 0.2 μg cellular fibronectin per milliliter per 10^6 cells (n = 6, p = 0.25, paired t test). Although these results failed to reveal differences between normal prepartum and postpartum sera, experiments with 10% sera from patients with preeclampsia did demonstrate differences between paired predelivery and postdelivery samples. Cells exposed to 10% predelivery preeclampsia sera released $1.6 \pm 0.2 \,\mu g$ cellular fibronectin per milliliter per 10^6 cells (n = 6) into the conditioned media, whereas conditioned media from identical cells treated with 10% postdelivery preeclamptic sera contained 1.1 ± 0.2 μg cellular fibronectin per milliliter per 10^6 cells (n = 6, p = 0.04, paired t test, Table HI). In a single experiment exposure of human renal microvascular endothelial cells to paired predelivery and postdelivery preeclamptic serum resulted in the release of 2.0 and 0.9 μg cellular fibronectin per milliliter per 106 cells, respectively.

Stimulation of human umbilical vein endothelial cell tissue factor activity was assessed with a chromogenic substrate assay. As described above, 1 µg/ml endotoxin induced an 18-fold increase in tissue factor activity. Predelivery normal sera exposure stimulated 24 ± 8 mU, whereas paired postdelivery sera resulted in tissue factor activity of 21 ± 8 mU/min/ 10^6 cells (n = 5, p = 0.70). Similarly, paired prepartum and postpartum preeclamptic sera had insignificant effects on human umbilical vein endothelial cell tissue factor activity (30 ± 14 vs 42 ± 16 mU/min/ 10^6 cells, respectively [n = 5, p = 0.47, paired t test], Table III).

Expression of endothelial cell von Willebrand factor was quantified with a whole-cell ELISA method. Human umbilical vein endothelial cells treated with endo-

toxin as a positive control increased by 2.6-fold their concentration of cell surface von Willebrand factor protein. However, paired analyses of predelivery and post-delivery sera from normal $(9.7 \pm 1.3 \text{ vs } 9.0 \pm 1.0 \text{ U}/10^6 \text{ cells } [n=6, p=0.54, \text{ paired } t \text{ test}])$ and pre-eclamptic $(9.0 \pm 0.8 \text{ vs } 9.2 \pm 0.7 \text{ U}/10^6 \text{ cells } [n=6, p=0.77, \text{ paired } t \text{ test}])$ patients revealed no differences in von Willebrand factor expression (Table III).

To assess whether absolute differences between predelivery preeclamptic and normal sera on human umbilical vein endothelial cellular fibronectin release could be demonstrated, additional experiments were performed and combined with the previous data to provide nine patients in each diagnostic group (Table II). Human umbilical vein endothelial cells exposed to 10% predelivery preeclamptic serum released 1.8 ± 0.1 μg cellular fibronectin per milliliter per 10^6 cells (n = 9)into the conditioned media. When cultures of the same cells were exposed to 10% normal prepartum pregnancy sera, the conditioned media contained 1.3 ± 0.1 μ g cellular fibronectin per milliliter per 10° cells (n = 9, Fig. 1). Analyses of these data with nonparametric (Mann-Whitney test, p = 0.01) or parametric (unpaired Student t test, p < 0.01) statistics demonstrated significant differences between the two diagnostic groups.

Comment

A panoply of clinical and biochemical findings relevant to endothelial cell function has been demonstrated in patients with clinical preeclampsia. The increased rate of disappearance of circulating Evans' blue dye, ¹³ decreased levels of prostacyclin, ¹⁴ pathognomonic renal biopsy findings, ¹⁵ and sensitive indicators of activation of the coagulation cascade ¹⁶ all suggest that vascular endothelial cell dysfunction occurs in patients with this disease. Previous studies that specifically focused on the expression of procoagulant proteins in vivo have documented that von Willebrand factor (factor VII—related antigen)¹⁷ and plasma cellular fibronectin

^{*}p Value for paired Student t test.

concentrations10, 18 are elevated in women with preeclampsia, even before the clinical manifestations of the syndrome.

This investigation was designed to determine if endothelial cell procoagulant activation could be used as a marker of cell perturbation in an in vitro model of preeclampsia. The results demonstrate that predelivery preeclamptic sera contain a factor(s) that stimulates the secretion or release of human endothelial cell cellular fibronectin to a greater extent than sera from normal pregnancies and suggest that the clinical observation of elevated plasma cellular fibronectin concentrations in preeclamptic women^{10, 18} might be due to the in vivo release of endothelial cell-derived cellular fibronectin by this factor(s). However, in this model of endothelial cell activation neither tissue factor nor von Willebrand factor expression appears to be increased preferentially by preeclamptic sera.

The present in vitro studies contrast with the elevated von Willebrand factor activity reported in the blood of preeclamptic women.17 Because we did not measure the release of von Willebrand factor into media, it is possible that increased release was not mirrored by increased surface expression of this factor. It is also possible that different experimental conditions, e.g., exposure of the cells to greater concentrations of serum or for longer incubation intervals, could have increased both von Willebrand factor and tissue factor. It is interesting, however, that under the same conditions endotoxin caused only a modest increase (33%) in cellular fibronectin whereas von Willebrand factor and tissue factor increased 2.6-fold and 18-fold, respectively.

A possible explanation for the current findings and our previous data demonstrating enhanced cytotoxicity3 and platelet-derived growth factor-stimulating effects⁴ of preeclamptic sera is the phenomenon of hemoconcentration in association with the reduced blood volume reported in this condition. This does not seem likely, as no statistical differences in hematocrit levels were detected between normal and preeclamptic groups, probably indicating the mild nature of the disorder in women in this study. The latter conclusion is supported by similar infant and placental weights, platelet counts, and serum creatinine concentrations in the two groups.

The presence of a factor(s) in the blood of preeclamptic women that can activate in vitro an endothelial function found in the clinical disorder in vivo supports the hypothesis that endothelial cell activation or injury in preeclampsia could be secondary effects of changes distant from the site of the perturbed endothelium. We propose that this factor(s) is derived directly or indirectly from the poorly perfused trophoblast characteristic of preeclampsia and that maternal

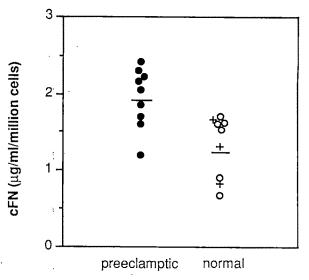

Fig. 1. Effects of predelivery pregnancy sera on human umbilical vein endothelial cell cellular fibronectin release in vitro. Human umbilical vein endothelial cells were exposed for 24 hours to media containing 10% predelivery pregnancy serum. Concentration of cellular fibronectin released into conditioned media was determined by ELISA. Serum samples from nine nulliparous preeclamptic patients (•), six nulliparous normal patients (0), and three parous normal patients (+) stimulated cellular fibronectin release as indicated. Horizontal bars, Mean cellular fibronectin concentrations for each patient group. Preeclamptic and normal patient groups differ significantly by Mann-Whitney and unpaired Student t tests (p = 0.01).

vascular endothelial cell injury or activation is a secondary, but essential, process in the pathogenesis of the preeclampsia syndrome.1

Potential role of endothelin-1 in normal and hypertensive pregnancies

Dimitrios S. Mastrogiannis, MD, PhD, William F. O'Brien, MD, Judith Krammer, MD, and Ray Benoit, BS

Tampa, Florida

Endothelins are the most potent naturally occurring vasoconstrictors yet discovered. Both normal and abnormal pregnancies are associated with significant changes in vascular smooth muscle; therefore the potential role of endothelin in pregnancy was investigated. Plasma immunoreactive endothelin-1 concentration was measured by radioimmunoassay in blood from women with normal pregnancy and preeclampsia and in cord blood from normal pregnancies. Endothelin-1 levels were elevated in pregnant women during labor when compared with levels in nonpregnant women and patients with normal pregnancies before labor. Preeclampsia in nonlaboring women before treatment was associated with higher endothelin values when compared with values in normal nonlaboring patients and women with preeclampsia after magnesium sulfate infusion. The umbilical venous concentration of endothelin was 10 times higher than normal pregnant levels and four times higher than levels in laboring patients. (AM J OBSTET GYNECOL 1991;165:1711-6.)

Key words: Endothelin, pregnancy, preeclampsia, labor, fetus

The role of the endothelium in modulating cardiovascular homeostasis via regulation of the vascular smooth muscle tone has been recognized recently. Endothelium regulates the reactivity of the smooth muscles through production of both vasodilators and vasoconstrictors. The endothelins are a group of vasoactive peptides first isolated from bovine aortic endothelial cells and are the most potent vasoconstrictors yet discovered. Three distinct human endothelin genes have been identified. Endothelin-1 is the only endothelin made by human endothelial cells. Endothelin-2 is produced in the kidney and endothelin-3 is mainly associated with neural tissue.

Endothelin appears to play a role in the pathogenesis of some forms of hypertension.⁴⁻⁶ Additionally, endothelin concentration is elevated in patients with acute myocardial infarction or vasculitis and in patients with uremia who are undergoing hemodialysis.⁷⁻⁹

Preeclampsia, a hypertensive disorder unique to pregnancy, is characterized by generalized vasoconstriction that is due, in part, to increased sensitivity of

vascular smooth muscle to the effects of vasopressors. ¹⁰ This is in contrast to normal pregnancy where the vascular bed is less sensitive to vasoconstrictors. ¹⁰ Several lines of evidence implicate endothelial cell injury as a basic pathogenic mechanism in preeclampsia resulting in impaired synthesis of vasodilators and a possible increase in the production of vasoconstrictors. ¹¹ Preliminary studies suggested that endothelin concentrations are elevated in women with preeclampsia, compared with controls. ^{12, 18} Both normal and hypertensive pregnancies are associated with significant changes in vascular smooth muscle tone; therefore the potential role of endothelin in various pregnancy conditions and pregnancy complications was investigated in this study.

Material and methods

One hundred twenty-eight plasma samples were prospectively collected from volunteers presenting for care at the University of South Florida and the Tampa General Hospital. Eighteen samples were collected from nonpregnant women of reproductive age without any medical or gynecologic complications. Forty-seven samples were collected from women with normal pregnancies at several gestational age intervals (11 samples from 6 to 12 weeks, 19 samples from 16 to 20 weeks, 9 samples from 26 to 33 weeks, and 8 samples from 35 to 42 weeks). Sixteen samples were collected from nonlaboring patients with preeclampsia before (n = 10) or after (n = 6) the institution of magnesium sulfate infusion. Sixteen samples were collected from patients in labor (eight patients with normal pregnancies and eight with preeclampsia). The collection of blood from hospital-

ized women was done on admission to the labor and delivery suite with the patients in the supine position and before any medications and thus reflects the first stage of labor in laboring women. Thirty-one samples were collected from the umbilical vein immediately after delivery in normal term pregnancies, before and after umbilical cord clamping.

All patients gave written informed consent as approved by the University of South Florida's Institutional Review Board. Preeclampsia was defined according to the following criteria: (1) nulliparity, (2) blood pressure $\geq 140/90$ mm Hg measured on two occasions at least 6 hours apart, (3) proteinuria of ≥ 30 mg/dl (defined as +1) by dipstick on random catheterized specimen, (4) no known history of hypertension before pregnancy, and (5) resolution of hypertension and proteinuria in the postpartum period.

All volunteers with normal pregnancies denied a history of hypertension or other medical complications. Patients with a history of illicit drug use or other medications were not included. Blood pressure measurements were obtained from patients in the sitting position after 15 minutes of rest, with phase IV Korotkoff sound used for the diastolic blood pressure. Obstetric and demographic data were recorded from the medical records. Blood samples were collected from each patient in the sitting position. Plasma was prepared from blood collected into chilled tubes containing 5 mg/ml ethylenediaminetetraacetic acid and 500 U/ml aprotinin. The plasma was separated by centrifugation and the samples were stored at -80° C until assayed. On the day of the assay, 2 ml of thawed plasma was acidified. with an equal volume 0.1% trifluoroacetic acid and 2N hydrochloric acid (pH 3), extracted over a C18 column, and eluted with 60% acetonitrile in 0.1% trifluoroacetic acid. Recoveries of 90% for both radiolabeled and unlabeled samples were observed. These extracts were evaporated to dryness under nitrogen and then assayed in duplicate with a specific radioimmunoassay (Peninsula Laboratories, Inc., Belmont, Calif.). Interassay and intraassay coefficient of variation for endothelin-1 was 7%.

Endothelin concentrations were corrected for midpoint displacement of each curve. We did not find differences in values from samples processed before or after freezing. Cross-reactivity with endothelin-2 and endothelin-3 was 7%. The person performing the radioimmunoassays was blinded as to the clinical condition of the patient. All data were expressed as mean \pm SD and were analyzed by the SAS (Statistical Analysis Systems, Cary, N.C.) statistical package, with the general linear model procedure for unbalanced designs, Duncan's multiple range test, unpaired and paired Student t tests, and χ^2 tests where appropriate. A probability of p < 0.05 was considered significant.

Results

The endothelin-1 concentration in normal nonpregnant women of reproductive age (mean age 32.4 ± 4.7 years, range 30 to 39 years) was 1.8 ± 0.6 pg/ml. There was no significant association between the subject's age and endothelin level concentrations for either nonpregnant or pregnant women and there was no significant difference in mean age between patients with normal pregnancies (28 ± 5 years) and nonpregnant controls.

All patients in the antepartum group remained normotensive and were delivered of normal infants at term. In Table I obstetric and demographic data are presented for the normal labor, preeclampsia, and umbilical venous sample groups. Systolic and diastolic blood pressure, urinary protein concentration, and serum uric acid concentration were significantly higher (p < 0.001) in the patients with preeclampsia. Endothelin-1 concentration in the nonpregnant and antepartum groups is shown in Fig. 1.

We did not observe a difference in endothelin concentrations between pregnant and nonpregnant patients (by SAS General Linear Model procedure for unbalanced designs). A possible effect of gestational

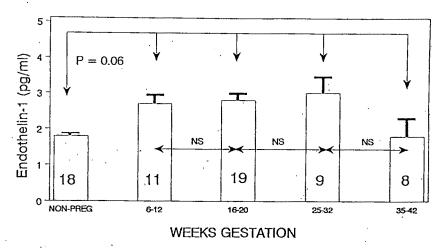

Fig. 1. Effect of pregnancy on peripheral venous plasma endothelin-1 levels (Duncan's multiple range test).

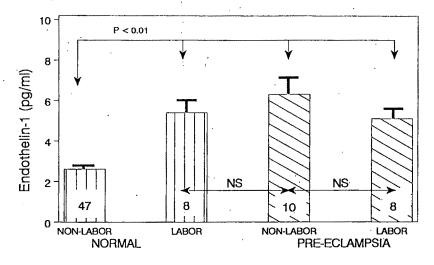

Fig. 2. Effect of labor on maternal venous plasma endothelin-1 in normal pregnancy and preeclampsia (Duncan's multiple range test).

age with increasing endothelin concentrations in the second and early third trimesters did not reach statistical significance (p = 0.06).

As noted in Fig. 2, levels of endothelin-1 were significantly higher in laboring women than in nonlaboring women and all patients with preeclampsia had concentrations higher than those in nonlaboring women with normal pregnancies. The increase noted in women with preeclampsia was similar to that associated with labor (SAS, General Linear Model procedure).

Women with preeclampsia (samples taken before magnesium sulfate infusion) had significantly elevated plasma endothelin concentrations when compared with samples obtained during magnesium sulfate infusion in nonpaired samples (p < 0.05) (Fig. 3). Similar results were found when paired samples were used (endothelin level before magnesium sulfate, $6.6 \pm 3.9 \text{ pg/ml}$; after magnesium sulfate, $4.75 \pm 2.9 \text{ pg/ml}$ (p < 0.02). Furthermore, endothelin was elevated in nonlaboring women with preeclampsia before treatment compared with patients with normal pregnancy (p < 0.001). Women with preeclampsia who labored had endothelin concentrations similar to those of laboring patients with normal pregnancies (Duncan's multiple range test) (Fig. 3). All patients with preeclampsia had hematocrits that were similar to those of patients with normal pregnancies.

In nonpaired samples the umbilical venous concentration of endothelin was 10 times higher than in normal pregnancies and four times higher than in laboring women (p < 0.001) (Fig. 4). Similar data were found in paired samples from mothers in labor and umbilical

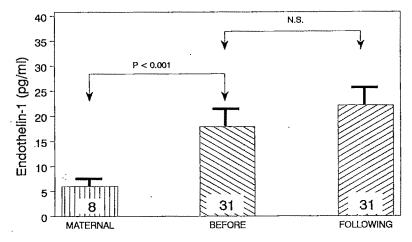

Fig. 4. Maternal venous and umbilical venous endothelin-1 levels before and after cord clamping (unpaired Student t test).

veins at delivery (maternal endothelin-1 4.0 ± 3.26 pg/ml, umbilical vein endothelin-1 17.6 ± 10.9 pg/ml). The concentration of endothelin was not different before or after cord clamping in paired samples (Fig. 4). Furthermore, no difference in umbilical venous samples from vaginal deliveries (n = 19) compared with cesarean sections (n = 12) was found.

Endothelin concentrations were not different in patients delivered by cesarean section and in those delivered vaginally.

No correlation between endothelin values (in the preeclampsia group) and level of maternal blood pressure or clinical severity was observed.

Comment

Endothelin-1 is the most active vasopressor substance yet discovered, with a potency 10 times that of angiotensin II.² Other properties of endothelin include in-

duction of uterine contractions, release of prostaglandins, and the release of endothelial-derived relaxing factors. 14-16 It is now believed that endothelin-1 binds to a specific membrane receptor leading to intracellular biochemical signals involving the activation of phospholipase C, with a release of inositol phosphates and diacylglycerol and mobilization of intracellular calcium. The resultant increase in intracellular calcium activates protein kinase C. 14, 17 Many substances, including thrombin, epinephrine, and the calcium ionophore A23187, cause the slow release of immunoreactive endothelin-1 from cultured endothelial cells. 2

In healthy humans plasma levels of endothelin-1 measured by radioimmunoassay have been estimated to range from 0.26 to 5 pg/ml. The concentration of endothelin-1 is likely to be much higher at the interface between the endothelium and smooth muscle. Therefore endothelin-1 is more likely to act as a local autacoid

rather than as a systemic regulating hormone.19 Paracrine effects of endothelin are very important, because many pharmacologic actions of endothelin-1 are not substantiated naturally by the systemic concentrations found, which are much lower than those required for the actions observed in vitro.18 This is particularly true because the increased concentrations of endothelin-1 are not necessarily related to the expected degree of vasoconstriction but are probably secondary effects of the simultaneous production of endothelial-relaxing factors and of vasodilatory prostaglandin release.18 It is also worth noting that the kidneys are 10 times more sensitive than other vascular regions to the vasoconstrictor effects of endothelin-1.20

The potent vasoconstrictor action of endothelin-1, together with elevated plasma levels found in myocardial infarction, vasculitis, and essential or pulmonary hypertension, contributes to the hypothesis that endothelin-1 may be involved in hypertensive states. 4-8 Its ability to stimulate the release of aldosterone and catecholamines from adrenal glands may contribute to hypertension, as would its ability to stimulate the release of renin.20, 21 In laboratory animals the sensitivity of renal artery segments to endothelin-1 was greater in rats with spontaneous hypertension than in normal animals.22

Normal pregnancy state is characterized by generalized refractoriness to vasopressor substances such as angiotensin II.10 On the contrary, pregnancy-induced. hypertension is characterized by widespread vasoconstriction.10 The dominant view is that the vasoconstriction results mainly or wholly from an abnormal sensitivity of vascular smooth muscle to the vasoconstrictive effect of pressor substances.

This study was concerned with endothelin-1 levels found in normal and preeclamptic pregnancies during labor, as well as in umbilical vein blood. Endothelin levels were elevated in women with preeclampsia without labor before any institution of treatment. This finding confirms that of Taylor et al.12 and Kamoi et al.13 Furthermore, we showed that magnesium infusion lowers the level of endothelin as compared with the preinfusion level. Surprisingly, no difference in endothelin values was found in laboring patients with preeclampsia compared with laboring patients with normal pregnancies.

We cannot explain at this time the high endothelin levels in normal pregnancies in the first stage of labor. It has recently been proposed, however, that endothelin-1 and oxytocin modulate calcium through independent receptors, and endothelin, like oxytocin, is an important modulator of uterine contractibility with possible implications in the physiologic characteristics of normal labor.28

The mechanism of endothelin elevation in preeclampsia is unknown, but there are a few possible ex-

planations. First, endothelin is basically a locally acting factor at the junction between endothelium and smooth muscle layer; therefore disruption and destruction of these anatomic boundaries can lead to a leak of endothelin from its local environment to the bloodstream with subsequently higher peripheral blood levels. Second, an abnormal production of endothelin by the affected endothelium might be a primary mechanism for the increase of endothelin locally and in the bloodstream. Third, increased production of endothelin from placental or fetal tissue in preeclampsia, or increased diffusion into the maternal circulation, might explain the elevated levels found in preeclampsia. Supporting the last hypothesis is evidence that the endothelin-1 receptor was identified in the membranes from a human placenta.²⁴ Endothelin is found in the amniotic fluid and it is shown to be synthesized not only by endothelial cells derived from human umbilical vein but also by amnion cells.25

Last, a defect of endothelin clearance could be a mechanism for the increased levels in preeclampsia. A different plasma volume of distribution in preeclampsia versus normal pregnancy would be an important factor. In our study the hematocrits did not differ significantly between the normotensive and preeclamptic groups. However, plasma albumin concentration may be a better indicator of plasma volume, independent of iron stores. Unfortunately, we did not test albumin concentrations in our patients.

Pharmacologic concentrations of endothelin-1 increase prostacyclin release from endothelial cells in vitro.15,26 This property may counterbalance its vasoconstrictor effects in vivo and serve as a negative feedback. Given the observation that the prostacyclin levels are reduced, in preeclampsia, then an abnormality of endothelin-prostacyclin interaction could exist.

We observed a lowering of endothelin values in patients during magnesium sulfate infusion. Recent in vitro studies have suggested that magnesium increases the prostacyclin production from endothelial cells, an observation that could not be supported in vivo as measured by systemic prostacyclin metabolite excretion in women who received magnesium sulfate infusion.27 However, an increase in renal prostacyclin production was observed in patients in preterm labor after magnesium sulfate infusion. Endothelin has a major action on the glomerulus and is synthesized by kidney cells, so that a change in the prostacyclin environment in the kidney could play some role in addition to the vasodilatory effect with subsequent release of the stretch stimulus of the vessel caused by magnesium sulfate. A recent study11 that also found increased levels of endothelin-1 in patients with preeclampsia failed to find a difference in the second-trimester levels of this peptide in women in whom preeclampsia eventually developed. These data support the hypothesis that endothelin elevation in preeclampsia is probably a secondary effect of another mechanism that initiates the change in endothelium that is basic to this disease.

The high concentration of endothelin-1 in the umbilical venous circulation in our study supports the previous report by Usuki et al. 25 and cannot be adequately explained at this time.24,26 Our data do not support a role in the contraction of umbilical vessels after delivery, because we did not find increased levels over a course of time (from before to after cord clamping). However, other investigators have suggested that endothelin-1 may contribute to fetal hemodynamic change, e.g., closure of the umbilical vessels occurring at delivery.28 These investigators collected cord blood after the clamping of the umbilical cord. As mentioned earlier, endothelin was found to be synthesized by endothelial cells derived from umbilical cords and amnion cells,25 suggesting that endothelin might play a significant role in the regulation of uteroplacental circulation. Endothelin was reported to contribute to the closure of the ductus arteriosus in lambs, emphasizing the importance of this peptide in gestation.29 Further study is needed to clarify this issue.

Endothelin-1-induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation

Leslie Myatt, PhD, Gretchen Langdon, BA, Anthony S. Brewer, BS, and Diane E. Brockman, MS

Cincinnati, Ohio

The vasoconstrictor peptide endothelin-1 (8 \times 10⁻¹⁰ to 1 \times 10⁻⁸ mol/L) significantly increased fetal-placental perfusion pressure in vitro in a cumulative manner from 30 \pm 2 to 123 \pm 25 mm Hg (mean \pm SEM, n=5, p<0.0005, analysis of variance). Accompanying this vasoconstriction was a corresponding reduction in fetal-placental perfusate flow rate. Measurement of thromboxane B₂ and 6-keto-prostaglandin F_{1a} in the fetal-placental perfusate revealed a significant reduction in their release (p<0.0096 and p<0.0004, analysis of variance, respectively) when corrected for flow rate. Neither the thromboxane synthesis inhibitor dazoxiben (10⁻⁶ mol/L) nor the thromboxane receptor antagonist SQ29548 (10⁻⁶ mol/L) was able to block the vasoconstrictor actions of endothelin-1. Therefore endothelin-1—induced vasoconstriction in the human fetal-placental circulation does not appear to be mediated by thromboxane release or action. The stimulus to eicosanoid release in the fetal-placental circulation may be hydrodynamic, i.e., flow or shear stress. (AM J OBSTET GYNECOL 1991;165:1717-22.)

Key words: Endothelin, thromboxane, placenta, vasoconstriction

The endothelins are a family of three distinct 21amino-acid peptides, endothelin-1, endothelin-2, and endothelin-3, which are coded for by three separate genes in the human rat and porcine genomes.1 Recently two distinct receptors for the endothelins have been cloned.2,3 The endothelins were first described as vasoconstrictor peptides produced by endothelial cells, although recently other cellular sites of synthesis and actions as diverse as oxytocic activity on the uterus4 and stimulation of peptide hormone release⁵ have been reported. The vasoconstrictor action of endothelin is characteristically long-acting (45 to 60 minutes) and is more pronounced on veins than on arteries.⁶ There is also evidence that threshold concentrations of endothelin increase sensitivity to other vasoconstrictors such as norepinephrine and serotonin.7.8 The action of endothelin is thought to be mediated by voltage-sensitive or, non-voltage-sensitive plasma membrane calcium channels.4

Reprint requests: L. Myatt, PhD, Department of Obstetrics and Gynecology, University of Cincinnati College of Medicine, 231 Bethesda Ave., Cincinnati, OH 45267-0526. 6/6/32384 There are reports that the contractile effect of endothelin-1 is mediated by thromboxane release and action. In isolated guinea pig airways⁹ and in rat vascular smooth muscle cells,¹⁰ endothelin stimulated thromboxane biosynthesis, whereas specific thromboxane receptor blockers⁹ or inhibitors of thromboxane synthesis¹⁰ attenuated the effects of endothelin-1. However, in human lung¹¹ the contractile effect of endothelin-1 does not appear to be due to release of prostaglandins or thromboxane A₂.

In the perfused human placenta, endothelin-1 has been shown to have a potent vasoconstrictive action¹² and to cause an apparent release in thromboxane during the contraction. Interestingly, the same workers¹³ previously had shown that the vasoconstrictive effect of bradykinin on the vessels of the perfused human cotyledon was associated with thromboxane release and action and could be partially attenuated with the thromboxane receptor antagonist SQ29548.

During vasoconstriction of the human fetal-placental circulation in vitro, a reduction in perfusate flow rate may account for the apparent increase in concentration of autocoids released into the perfusate. Therefore we have measured both thromboxane and prostacyclin release by the human fetal-placental circulation during endothelin-1—induced vasoconstriction in relation to perfusate flow rate. Further, we have used inhibitors of thromboxane synthesis and action to determine the role of thromboxane in endothelin-1—induced vasoconstriction.

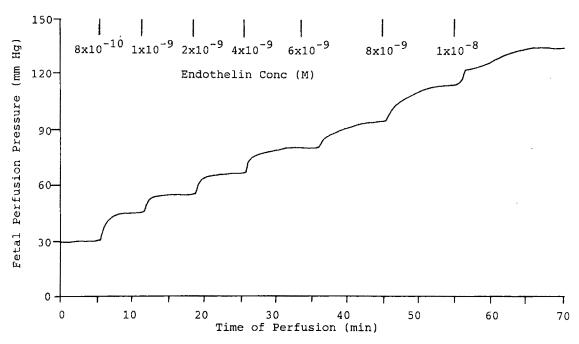

Fig. 1. Representative experiment of effect of endothelin-1 (8 \times 10⁻¹⁰ to 3.18 \times 10⁻⁸ mol/L cumulative concentration) on fetal-placental perfusion pressure.

Material and methods

Placentas were collected immediately after normal vaginal delivery or elective cesarean section, under a protocol approved by the institutional review board, and were transported to the perfusion laboratory in the labor and delivery area. A suitable third- or fourthorder chorionic artery and corresponding vein of an intact cotyledon were cannulated, as we have previously described,14 at a point immediately before passage of the vessels through the chorionic plate. The maternal intervillous space was cannulated with two butterfly needles inserted through remnants of the spiral arteries in the basal plate. The effluent from the intervillous space was collected by gravity into a Plexiglas cone over which the cotyledon was placed, maternal surface downward. Perfusion medium, except where stated, was tissue culture medium 199 containing 5% polyvinylpyrrolidone 40 and 0.1% bovine serum albumin as oncotic agents and with 20 IU/ml heparin and 48 μg/ml gentamicin added. Medium was pH 7.4 with bicarbonate and gassed with 95% oxygen and 5% carbon dioxide at 37° C. Flow rates on the perfusion pumps were 4 (fetal) and 10 (maternal) ml/min except where stated. Lateral pressure was measured in fetal and maternal inflow lines adjacent to the point of cannulation. Data on pressure, inflow and outflow Po2, and pH were sampled every second and stored on an IBM PS2 system with Asystant Plus software (Asyst Technologies, Rochester, N.Y.).

The effects of endothelin-1 on perfusion pressure and eicosanoid release in the fetal-placental circulation was studied. After an equilibration period of at least 30 minutes, endothelin-1 (8 \times 10⁻¹⁰ mol/L) was infused as a 2 ml bolus to the fetal-placental circulation. When perfusion pressure had increased, the next concentration of endothelin-1 was infused (8 to 10-10 to 1×10^{-8} mol/L) and cumulative increases in perfusion pressure recorded. Both maternal and fetal perfusates were collected in fractions corresponding to a 5-minute duration of flow. The volume collected in each fraction was then measured to calculate outflow from each circulation before the perfusate fractions were stored at -20° C for subsequent assay of thromboxane (TxB₂) B₂ and 6-keto-prostaglandin (PGF₁₀) F₁₀, the stable hydrolysis products of thromboxane A2 and prostacyclin, respectively, with radioimmunoassays we have previously described.15

To determine if thromboxane release and action were mediators of endothelin-1—induced vasoconstriction, the effects of a thromboxane synthetase inhibitor and a thromboxane receptor antagonist on endothelin-1 action were studied. The vasoconstrictor response to endothelin-1 (3 \times 10⁻⁸ mol/L) was measured before and after addition of the thromboxane synthetase inhibitor dazoxiben (10⁻⁶ mol/L) to both maternal and fetal perfusate. A 30-minute period of equilibration with dazoxiben was allowed before the second infusion of endothelin-1. Thromboxane receptor antagonist studies were conducted as follows: After a 30-minute equilibration period, vasoconstrictor responses to bolus infusion of the thromboxane mimetic U46619 (2.3 \times 10⁻⁷ mol/L) and endothelin-1 (3 \times 10⁻⁸

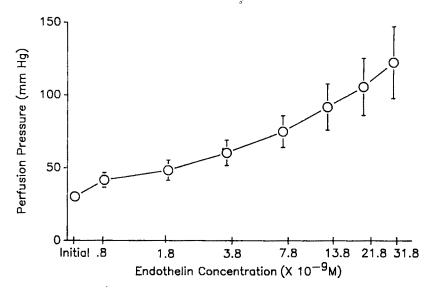

Fig. 2. Effect of endothelin-1 on fetal-placental perfusion pressure. Cumulative perfusion pressure on infusion of increasing concentrations (8×10^{-10} to 1×10^{-8} mol/L [8×10^{-10} to 3.18×10^{-8} mol/L cumulative]) of endothelin-1 on fetal-placental circulation. Mean \pm SEM, n = 5. One way analysis of variance showed significant increase in perfusion pressure with increasing concentrations of endothelin-1 (p < 0.0005).

mol/L) were recorded. After reequilibration of perfusion pressure after addition of this endothelin-1, both fetal and maternal perfusion media were changed to media containing SQ29548 (10⁻⁶ mol/L) and perfusion continued. After a 30-minute equilibration period with SQ29548, the responses to infusion of U46619 and endothelin-1 were again determined. All experiments were repeated in at least three separate placentas.

The significance of changes in perfusion pressure and eicosanoid synthesis on addition of increasing concentrations of endothelin-1 was determined by analysis of variance, and the effects of thromboxane antagonists were determined by paired t tests. U46619 was kept as a 10^{-3} mol/L stock in ethanol at -20° C and endothelin-1 was kept at 10^{-5} mol/L in 0.5 mol/L acetic acid at -70° C. Dazoxiben was kept at 10^{-3} mol/L in saline solution at 4° C and SQ29548 at 10^{-3} mol/L in ethanol at 4° C. Appropriate dilutions were made before each use.

Results

Endothelin-1 (8 × 10⁻¹⁰ to 1 × 10⁻⁸ mol/L [8 × 10^{-10} to 3.18×10^{-8} mol/L cumulative concentration]) gave a significant cumulative increase in fetal-placental perfusion pressure (p < 0.0005, analysis of variance from 30 ± 2 to 123 ± 25 mm Hg (Figs. 1 and 2). As shown in Fig. 1, the increase in perfusion pressure on addition of endothelin-1 was sustained (45 to 60 minutes) such that only cumulative increases could be measured. Accompanying the increase in perfusion pressure was a decrease in fetal venous perfusate outflow from an initial measured venous return of 3.1 ± 0.1

ml/min to 0.19 ± 0.08 ml/min (Fig. 3). Although the fetal perfusion pump flow rate was nominally set at 4 ml/min, fetal venous outflow was measured to accurately quantify fetal flow rate. The resting flow rate of 3.1 ml/min probably results from some loss of perfusate by transfer to the maternal circuit. Interestingly, there was a slight increase in flow rate, although not significant, at the lower concentration of endothelin-1.

Direct measurement of TxB_2 and 6-keto-PGF_{1 α} concentrations in the fetal venous perfusate showed an apparent increase in TxB_2 concentrations in the perfusate at the higher concentrations of endothelin-1 (data not shown) but with no apparent change in 6-keto-PGF_{1 α} concentrations. However, when corrections for the reduction in flow rate during endothelin-1-induced vasoconstriction were made (Fig. 4), there was an obvious decrease in the release of both TxB_2 from 987 ± 182 to 56 ± 10 pg/min (p < 0.0096, analysis of variance) and 6-keto-PGF_{1 α} from 332 ± 74 to 33 ± 11 pg/min (p < 0.0004, analysis of variance).

Addition of the thromboxane synthesis inhibitor dazoxiben (10^{-6} mol/L) to perfusate did not alter the vasoconstrictor response to endothelin-1 (3×10^{-8} mol/L). The vasoconstrictor responses to endothelin-1 before and after dazoxiben were 18.0 ± 7.4 and 25.1 ± 13.6 mm Hg, respectively (mean \pm SE, n = 5). However, addition of the thromboxane receptor antagonist SQ29548 (10^{-6} mol/L) significantly attenuated the vasoconstrictor response to U46619 (2.3×10^{-7} mol/L) in this preparation (Fig. 5 and Table I) but had no effect on the vasoconstrictor response to endothelin- $1 (3 \times 10^{-8}$ mol/L). The slightly greater and more vari-

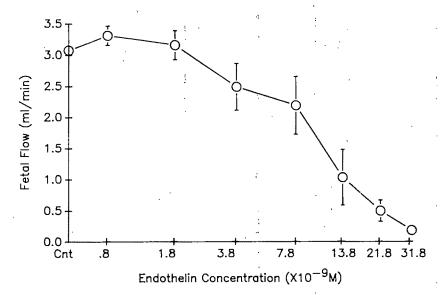

Fig. 3. Effect of endothelin-1 on fetal-placental perfusate flow rate. Fetal-placental flow rate was determined by measuring fetal venous effluent volume during endothelin-1-induced vasoconstriction. Mean \pm SEM, n=5.

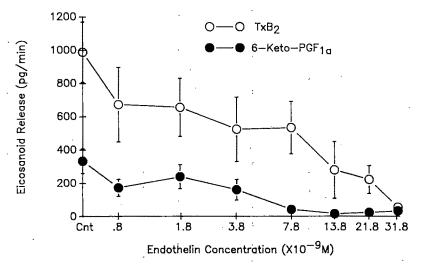

Fig. 4. TxB_2 and 6-keto-PGF_{1 α} release during endothelin-1 induced vasoconstriction. TxB_2 and 6-keto-PGF_{1 α} concentrations were measured by radioimmunoassay in fetal venous perfusate fractions collected during endothelin-1-induced vasoconstriction. Eicosanoid release was corrected for flow rate and expressed as picograms per minute. Mean \pm SEM, n=5. One-way analysis of variance showed significant reduction in TxB_2 release (p<0.0096) and 6-keto-PGF_{1 α} release (p<0.0004) with endothelin-1-induced vasoconstriction.

able response to endothelin-1 after either dazoxiben or SQ29548 may have been due to potentiation of the vasoconstrictor effect by the first endothelin-1 injection and by the difficulty in regaining baseline pressure after endothelin-1 injection that gave a very long-lasting effect (45 to 60 minutes).

Comment

In agreement with a previous report, ¹² we found that endothelin-1 was a potent vasoconstrictor of the human

fetal-placental circulation in vitro. The response to endothelin-1 is of sustained duration, purportedly acting by voltage-dependent or voltage-independent calcium channels; therefore only cumulative changes in perfusion pressure could be recorded. There was a reduction in perfusate flow rate (measured as fetal outflow) through the fetal circulation accompanying this vasoconstriction. This reduction in flow rate led to the apparent increase in thromboxane concentrations measured directly in perfusate at the higher endothelin

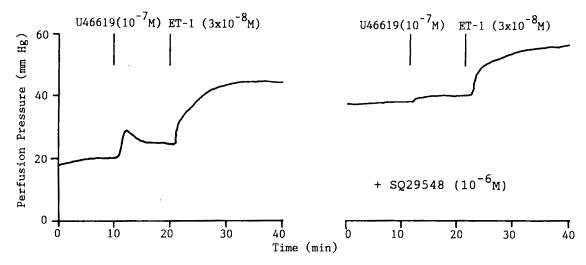

Fig. 5. Representative experiment of effect of SQ29548 (10⁻⁶ mol/L) on vasoconstrictor responses to U46619 and endothelin-1. Vasoconstrictor response to U46619 (2.3 × 10⁻⁷ mol/L) and endothelin-1 (3 \times 10⁻⁸ mol/L) is shown in same placenta before and during perfusion with thromboxane receptor antagonist SQ29548 (10⁻⁶ mol/L).

concentrations and also presumably in the previous report by Wilkes et al.12 Because endothelin-1 is a more potent constrictor of veins than arteries,6 it is possible that the effect of endothelin-1 is on the venous side of the cotyledonary vascular tree and that the reduction in fetal outflow relative to inflow may arise in part from bulk flow of water from the fetal to the maternal circulation as a result of the hydrostatic pressure difference resulting from vasoconstriction in the fetal circulation. We do not feel that the loss of fetal outflow was due to rupture of the fetal vasculature and a direct leak to the maternal circulation, as when this occurs, very erratic variations or large falls in perfusion pressure are seen. Correction for perfusate flow rate through the fetal-placental circulation revealed a reduction in both thromboxane and prostacyclin metabolite release per minute during endothelin-1-induced vasoconstriction. We have previously shown that increasing perfusate flow rate through the fetal-placental circulation led to increased release of both thromboxane and prostacyclin.16 Therefore, hydrodynamic forces (flow or shear stress) through the fetal-placental vessels may be the stimulus to eicosanoid release.

In some studies of different vasculatures, endothelin action has been shown to be mediated by thromboxane release and action by specific receptors,9,10 although other studies have demonstrated effects independent of thromboxane.11 We have clearly shown that inhibition of thromboxane synthesis by dazoxiben did not affect endothelin-1 action in the fetal-placental vasculature. Similarly, SQ29548, which effectively blocks thromboxane action by its receptor, was unable to prevent endothelin-1-induced vasoconstriction in the hu-

An endothelial cell model for the investigation of the molecular regulation of fetal vascular tone

Donald J. Dudley, MD, Sharie LaMarche, BS, and Murray D. Mitchell, DPhil Salt Lake City, Utah

Human umbilical vessels are not innervated, and hence regulation of tone in these vessels must come from locally derived vasoactive substances such as prostacyclin. To evaluate the regulation of prostacyclin production by human umbilical vein endothelial cells, we incubated confluent cultures of these cells with various concentrations of inflammatory mediators (endotoxin, interleukin-1 β , and tumor necrosis factor), protein kinase C agonists (phorbol 12-myristate 13-acetate, phorbol 12,13-dibutyrate), and calcium ionophores (A-23187 and ionomycin). Human umbilical vein endothelial cells were prepared from term pregnancies, and confluent cultures were incubated with test substances for 16 hours. Prostacyclin was measured as its metabolite 6-keto-prostaglandin $F_{1\alpha}$ by radioimmunoassay. Concentration-related increases in 6-keto-prostaglandin $F_{1\alpha}$ production were observed in response to endotoxin, cytokines, phorbol esters, and calcium ionophores. We conclude that human umbilical vein endothelial cell prostacyclin production is influenced by several intracellular messengers and that human umbilical vein endothelial cells may provide a useful in vitro model for investigating the physiology and pathophysiology of umbilical vessel vascular tone. (AM J OBSTET GYNECOL 1991;165:1723-6.)

Key words: Endothelium, prostacyclin, cytokine, calcium, protein kinase C

Because human umbilical vessels are not innervated, regulation of vascular tone in the umbilical cord must be dependent on local vasoactive substances, presumably derived from and produced by endothelium. Products of arachidonic acid metabolism through the cyclooxygenase pathway may be important in controlling the tone of umbilical vessels.^{1, 2} Prostacyclin, a potent vasodilator, is the primary cyclooxygenase product of human umbilical vein endothelium and may be of importance physiologically and pathophysiologically in the regulation of fetoplacental hemostasis and blood flow.^{3,5}

The purpose of this study was to determine the regulation of prostacyclin production (as measured by its stable metabolite 6-keto-prostaglandin $F_{1\alpha}$ [6-keto-PGF_{1\alpha}]) by primary cultures of normal human umbilical vein endothelial cells in culture. We chose to evaluate the effects of inflammatory mediators, because their release during infection in the perinatal period may contribute significantly to subsequent neonatal mortality and morbidity. ^{6, 7} Additionally, we have evaluated the effects of protein kinase C modifiers and calcium ionophores on 6-keto-PGF_{1\alpha} production, because these intracellular signaling systems have significant effects

on arachidonic acid metabolism in other gestational cells and tissues.⁸⁻¹² An understanding of the regulation of arachidonic acid metabolism by primary cultures of human umbilical vein endothelial cells could provide significant insight into the determinants of normal and abnormal fetal umbilical vascular tone and blood flow.

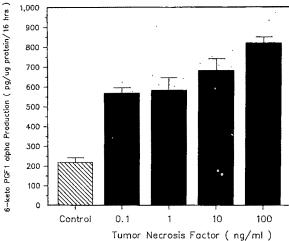

Material and methods

Material. M199 was obtained from Gibco, Long Island, NY; Dulbecco's modified Eagle's medium, Ham's F12/Dulbecco's modified Eagle's medium (1:1), and fetal calf serum were purchased from Irvine Scientific, Santa Ana, Calif. Penicillin (10,000 U/ml), streptomycin (10,000 μg/ml), and amphotericin B (25 μg/ml) solution was purchased from Gibco, Grand Island, N.Y. Cell culture plates were from Costar, Cambridge, Mass. Phorbol 12-myristate 13-acetate, phorbol 12,13-dibutyrate, 4α -phorbol didecanoate, A23187, ionomycin, and bacterial endotoxin from *Escherichia coli* were purchased from Sigma Chemical Company, St. Louis. Interleukin-1β (IL-1β) and tumor necrosis factor were purchased from R and D Systems, Minneapolis, Minn.

Primary human umbilical vein endothelial cells. Endothelial cells were obtained from the umbilical vein of normal term human pregnancies by the method of Jaffe¹⁵ and grown in M199 culture medium with 20% normal pooled heat-inactivated human serum and antibiotics, as we have previously described. ¹⁴ Confluent monolayers of human umbilical vein endothelial cells in 24-well culture plates were used for all the experiments described.

Experimental conditions. Dilutions of each bioactive

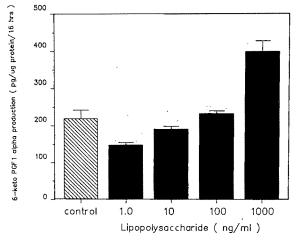

Fig. 1. Effect of inflammatory mediators on 6-keto-PGF_{ta} production (mean \pm SEM, N=4) by human umbilical vein endothelial cells. *Top panel*, IL-1 β (p < 0.01, control vs all concentrations). *Middle panel*, Tumor necrosis factor (p < 0.01, control vs all concentrations). *Bottom panel*, Lipopolysaccharide (p < 0.01, control vs 1000 ng/ml).

substance tested were made in experimental medium (Dulbecco's modified Eagle's medium and Ham's F12/Dulbecco's modified Eagle's medium [1:1] with 10% fetal calf serum and antibiotics) and then applied to the cells after the culture medium was aspirated.

Each condition was tested in quadruplicate, and in each experiment there were control cells (experimental medium only) and cells that underwent thrombin (international units per well) stimulation. Only plates of endothelial cells that demonstrated an adequate response to thrombin (at least two times control 6-keto-PGF_{1a} production) were considered valid and are represented in the results.

6-Keto-PGF_{1α} **production.** Cells were incubated with or without test substances for 16 hours, and media were collected and stored frozen until assayed for 6-keto-PGF_{1α} by radioimmunoassay, with an antiserum obtained from Advanced Magnetics, Cambridge, Mass. Total cell protein was determined by the method of Lowry et al. Results are expressed as picograms 6-keto-PGF_{1α} production per microgram protein per 16 hours. Statistical differences were assessed by the Student t test.

Results

Both IL-1 β and tumor necrosis factor induced significant concentration-dependent increases in 6-keto-PGF_{1 α} production by human umbilical vein endothelial cells (Fig. 1). Notably, IL-1 β was a particularly potent stimulator of 6-keto-PGF_{1 α} production, inducing a four-teenfold increase at just 0.01 ng/ml. Conversely, lipopolysaccharide stimulated 6-keto-PGF_{1 α} production only at the highest concentration tested (1000 ng/ml).

Both of the active phorbol esters phorbol 12-myristate 13-acetate and phorbol 12,13-dibutyrate stimulated significant increases in 6-keto-PGF_{1 α} production by human umbilical vein endothelial cells (Fig. 2). The inactive phorbol ester 4 α -phorbol didecanoate, however, had no effect on prostacyclin production.

Treatment with ionomycin and A23187 caused concentration-dependent increases in 6-keto-PGF_{1 α} production by human umbilical vein endothelial cells (Fig. 3). Relatively high concentrations of A23187 were required to stimulate significantly the production of prostacyclin, perhaps reflecting the relatively nonspecific action of this ionophore. Ionomycin was another potent stimulator of 6-keto-PGF_{1 α} production.

Comment

Our results indicate that prostacyclin production by human umbilical vein endothelial cells can be stimulated by a wide variety of agonists by means of different signal transduction mechanisms. Phorbol esters have been found to stimulate *de novo* synthesis of cyclooxygenase, ¹⁶ and our data support the finding that phorbol esters stimulate prostacyclin production in human umbilical vein endothelial cells. However, the exact signaling linkage between protein kinase C activation and arachidonic acid metabolism remains unclear. Increases in intracellular calcium mediated by the calcium ionophores A23187 and ionomycin also stimulate prostacyclin production. This action is presumed to be the

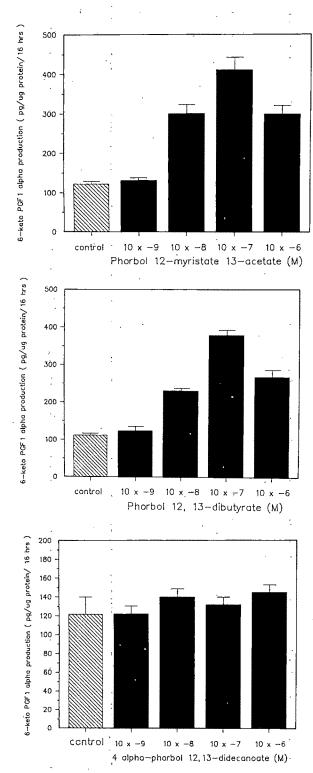

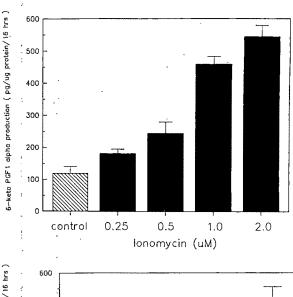

Fig. 2. Effect of phorbol esters on 6-keto-PGF_{1α} production (mean \pm SEM, N=4) by human umbilical vein endothelial cells. Top panel, Phorbol 12-myristate 13-acetate (p < 0.01, control vs 10⁻⁸, 10⁻⁷, and 10⁻⁶ mol/L). Middle panel, Phorbol 12,13-dibutyrate (p < 0.01, control vs 10^{-8} , 10^{-7} , and 10^{-6} mol/L). result of intracellular calcium activation of phospholipases, thus increasing available substrate for the cyclooxygenase enzyme. Inflammatory cytokines also were found to be potent stimulators of prostacyclin

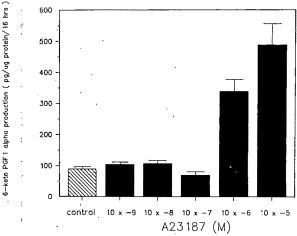

Fig 3. Effect of calcium ionophores on 6-keto-PGF_{ac} production (mean \pm SEM, N=4) by human umbilical vein endothelial cells. Upper panel, Ionomycin (p < 0.05, control vs all concentrations). Lower panel, A23187 (p < 0.05, control vs 10^{-7} and 10^{-6} mol/L).

production, and the cyclooxygenase gene has been reported to be induced in endothelial cells by IL-1B.17 However, the signaling mechanisms linking the IL-1 receptor to specific gene activation is not completely known but is thought to be dependent on activation of phospholipases.18

Regardless of mechanism, IL-1B appears to be a particularly potent stimulator of prostacyclin production, because concentrations as low as 0.01 ng/ml result in significantly elevated prostacyclin production. Interestingly, endotoxin has only a modest effect even at relatively high concentrations (1000 ng/ml). These data suggest that increased concentrations of prostacyclin resulting from IL-1\beta stimulation may play a role in the hypotension that is characteristic of gram-negative bacterial neonatal sepsis.6,7 This finding is consistent with previous reports that an overly exuberant host response to bacterial invasion, as reflected by production of inflanimatory cytokines, is responsible for several of the serious sequelae characteristic of sepsis in adult patients.^{19,20} Our findings confirm that such a mechanism in fetal tissue is possible. However, it is uncertain whether this may account for the neonatal signs and symptoms of sepsis or provide further rationale for the development of interventional therapies designed to interrupt the cytokine-mediated inflammatory cascade.^{21, 22}

It is readily evident that endothelial cells obtained from the umbilical cords of term pregnancies provide a useful model for the understanding of signal transduction mechanisms in general, but human umbilical vein endothelial cells may not be entirely appropriate to study adult endothelial cell properties and functions. For example, we have previously shown that human umbilical vein endothelial cells are not useful as a model to evaluate the effects of antiphospholipid antibodies on prostaglandin production.14 However, we believe that our data indicate that primary cultures of human umbilical vein endothelial cells may be a useful model for the understanding of the molecular events that regulate fetal vascular tone. Although we limited these studies to the regulation of endothelial cell prostacyclin production, the regulation of other vasoactive substances (e.g., endothelins) can be studied in a similar fashion.

We thank the staff of our labor and delivery unit for assistance with obtaining umbilical cords. We are grateful to Mary Ann Isenhart for expert editorial assistance and Samuel S. Edwin for artwork.

In utero diagnosis of congenital varicella zoster virus infection by chorionic villus sampling and polymerase chain reaction

Nelson B. Isada, MD,^a David P. Paar, MD,^c Mark P. Johnson, MD,^{a,c} Mark I. Evans, MD,^{a,c} Wolfgang Holzgreve, MD,^d Faisal Qureshi, MD,^b and Stephen E. Straus, MD^c

Detroit, Michigan, Münster, Germany, and Bethesda, Maryland

Varicella zoster virus infection acquired in pregnancy is reported to cause fetal damage in 5% to 10% of cases. We used polymerase chain reaction to attempt molecular diagnosis of fetoplacental varicella zoster virus infection in two patients. Tissue obtained by chorionic villus sampling in the second trimester was analyzed by polymerase chain reaction with a varicella zoster virus—specific primer, ORF-63, and was found to be positive in both patients. Viral cultures were negative. One patient elected pregnancy termination at 23 weeks. Southern blot hybridization of neonatal brain tissue for varicella zoster virus was negative. The second patient carried the pregnancy to term and was delivered of a normal infant. Varicella zoster virus immunoglobulin M and viral cultures were negative. The presence of viral deoxyribonucleic acid sequences in placental tissue does not correlate with fetal disease. (AM J OBSTET GYNECOL 1991;165:1727-30.)

Key words: Chorionic villus sampling, polymerase chain reaction, varicella zoster virus

Varicella zoster virus infection acquired in pregnancy is reported to cause fetal damage in 5% to 10% of cases. ^{1, 2} Antenatal diagnosis of the fetal varicella syndrome has been achieved by ultrasonographic detection of fetal anomalies and by cordocentesis for the detection of fetal immune globulin production. ^{3, 4} Here we report the use of the polymerase chain reaction to attempt molecular diagnosis of fetoplacental varicella zoster virus infection.

Case reports

Case 1. Chickenpox lesions developed in a 17-year-old primigravid woman with onset at 4 to 5 weeks' gestational age. Lesions lasted 1 week. She desired evaluation for possible fetal infection and was seen in consultation at 19 weeks. Ultrasonographic examination showed no fetal defects. Viral cultures from chorionic villus sampling and amniocentesis were negative. However, polymerase chain reaction was positive. The patient elected pregnancy termination at 23 weeks' gestation. Cordocentesis was attempted but was not successful. The fetus was delivered after urea amnioinfusion and prostaglandin induction of labor. Autopsy of the fetus was unremarkable. Cord blood varicella zoster virus immunoglobulin M was unobtainable. Southern blot analysis of fetal brain tissue dem-

From the Departments of Obstetrics and Gynecology, Pathology, and Molecular Biology and Genetics, Hutzel Hospital/Wayne State University, Detroit, the Institutes for Humangenetik, Münster, and the Medical Virology Section, Laboratory of Clinical Investigation, National Institute of Allergy and Infectious Diseases, Bethesda.' Isada, MD, Division of Reproductive Genetics, Hutzel Hospital, 4707 St. Antoine, Detroit, MI 47201. 6/6/33548

onstrated no varicella zoster virus-specific genomic material.

Case 2. In a 30-year-old woman, gravida 2, para 2, chickenpox developed at 8 weeks' gestational age. Lesions lasted 1 to 2 weeks. She desired evaluation for possible fetal infection. After consultation at 20 weeks, she underwent transabdominal chorionic villus sampling and amniocentesis. Results of ultrasonographic evaluation were normal. Viral cultures on chorionic villus sampling and amniotic fluid material were negative. Polymerase chain reaction was positive for the presence of viral genome in trophoblast. She declined cordocentesis. Serial ultrasonographic examinations gave negative results. The patient was delivered of a healthy infant at term. Cord blood varicella zoster virus immunoglobulin M was negative and placental viral cultures were negative.

Material and methods

Deoxyribonucleic acid (DNA) extraction. The protocol of Miller et al.,5 was modified to extract deoxyribonucleic acid (DNA) from chorionic villus sampling and concurrently from control whole human fibroblasts (Whittaker MA Bioproducts, Walkersville, Md.). The tissue samples or whole human fibroblasts were placed in 2.25 ml of cold nuclear lysis buffer (0.5 mol/L Tris hydrochloride, pH 8; 20 mmol/L ethylenediaminetetraacetic acid, pH 8; and 10 mmol/L sodium chloride and homogenized with a Tissumizer homogenizer (Tekmar Co., Cincinnati). The cell lysates were digested at 50° C for 45 minutes with 0.125 ml of 20% sodium dodecyl sulfate and 0.125 ml protease K (20 mg/ml stock in distilled water). A total of 0.625 ml of saturated sodium chloride (6 mol/L) was added, and the lysate was shaken vigorously. The mixture was centrifuged

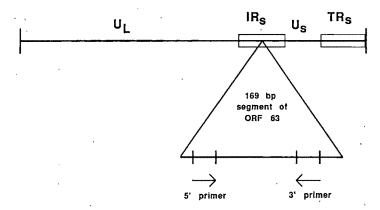

Fig. 1. Schematic map of varicella zoster virus genome showing location of amplified segment of open reading frame (ORF) 63 relative to unique long (U_L) , inverted repeat short (IR_S) , unique short (U_S) , and terminal repeat short (TR_S) elements. Also shown are locations of primer pairs used in polymerase chain reaction.

for 20 minutes at 2000 rpm, and the supernatant was transferred to another tube. DNA was precipitated by the addition of 5 ml of 100% ethanol and transferred to another tube with a plastic pipette. The DNA was washed once with 70% ethanol, dried in a Speed Vac (Savant Instruments, Inc., Hicksville, N.Y.), and suspended in Tris hydrochloride—ethylenediaminetetraacetic acid, pH 8; the concentration was determined with a DU-40 spectrophotometer by absorption at 260 nm (Beckman Instruments, Inc., Fullerton, Calif.).

Polymerase chain reaction. Oligonucleotide primers (18 mer) were chosen from published sequences of varicella zoster virus DNA and were synthesized with a Gene Assembler Plus DNA synthesizer (Pharmacia LKB Biotechnology, Inc., Piscataway, N.J.).6, 7 The primers (upstream 5' CGGTTGGATGTTAACGGA 3'; downstream 5' CCCGACGACTGTGGAATA 3') were designed to amplify a 169 bp segment of the gene encoding open reading frame 63. Fig. 1 shows a diagramatic representation of primer location within the varicella zoster virus genome. This schematic map shows the location of the amplified segment of open reading frame 63 relative to the unique long, inverted repeat short, unique short, and terminal repeat short elements. Also shown are the locations of the primer pairs used in the polymerase chain reaction. The 5' primer includes bases 110,603 through 110,720; the 3' primer includes bases 110,654 through 110,771.

Polymerase chain reaction was performed with a commercial kit (GeneAmp, Perkin Elmer Cetus, Norwalk, Conn.). All reactions were performed in 100 µl volumes and consisted of 0.5 µg of chorionic villus sampling tissue DNA or whole human fibroblasts DNA or 1 ng of purified varicella zoster virus virion DNA, 1 µmol of each primer, 200 µmol of each deoxynucleotide triphosphate (deoxyadenosine triphosphate,

deoxycytidine triphosphate, deoxyguanosine triphosphate, and deoxythynidine triphosphate), 2.5 units of *Thermus aquaticus* DNA polymerase, 0.010 mol/L Tris—hydrochloric acid, 0.050 mol/L potassium chloride, and 0.015 mol/L magnesium chloride. The reaction mixtures were overlayed with 50 µl of mineral oil and placed in an automated thermal cycler (Perkins Elmer Cetus). The reaction conditions consisted of denaturation at 94° C for 1 minute, primer annealing at 50° C for 1 minute, and primer extension 72° C for 1 minute.

Analysis of polymerase chain reaction products. One microliter of 10× buffer (25% glycerol, 2.25 mmol/L ethylenediaminetetraacetic acid, 0.4 mmol/L Tris-hydrochloric acid, and 0.5% sodium dodecyl sulfate) was added to 10 µl aliquots of the polymerase chain reaction mixtures, and gel electrophoresis was performed with 1% agarose gel in buffer at a current of 100 mA. The gel was denatured for ½ hour in 1 mol/L sodium chloride and 0.5 mol/L sodium hydroxide and then neutralized for 1/2 hour in 0.5 mol/L Tris-hydrochloric acid, pH 7.5, and 1.5 mol/L sodium chloride. The DNA from the gel was transferred to a Nytran membrane (Schleicher and Schuell, Keene, N.H.) with a Posiblot transfer system (Stratagene, La Jolla, Calif.). The EcoRI-E restriction fragment of varicella zoster virus DNAs was used as the hybridization probe. It was radiolabeled with deoxycytidine triphosphate-5'(α-phosphorus 32), triethylammonium salt (Amersham, Arlington Heights, Ill.) to a specific activity of at least 103 to 106 cpm/µg, and Southern hybridization⁸ was performed. The membrane was autoradiographed for 4 hours at -70° C with Kodak X-OMAT AR film (Eastman Kodak, Rochester, N.Y.). The autoradiograph was developed in a Kodak X-OMAT M20 automated processor (Eastman Kodak).

Results

In Fig. 2, lane 1, labeled varicella zoster virus shows a 169 bp band, indicating that the chosen primers amplified the desired product. Two bands of higher molecular weight in this lane represent nonspecific hybridization of viral DNA. Lane 2 contains an unrelated sample. The lane labeled WHF contains the products of reactions with concurrently processed tissue culture cells. The lack of discernible band indicates that the primers chosen for amplification of viral DNA do not amplify equivalent amounts of human genomic DNA. Importantly, the absence of a band also indicates that the DNA samples were not contaminated with exogenous viral DNA during the extraction process and subsequent handling. The lanes labeled CVS 1 and CVS 2 both contain the desired 169 bp fragment of DNA, suggesting that varicella zoster virus DNA was present in both chorionic villus sampling samples.

Comment

Fetal varicella syndrome is characterized by cicatrix formation, growth retardation, limb defects, cortical atrophy, chorioretinitis, and microcephaly. This syndrome is distinct from that of neonatal varicella acquired from a third-trimester maternal varicella infection. In fetal varicella syndrome defects have been attributed to maternal varicella zoster virus infection occurring in the first and second trimesters. Laforet and Lynch⁹ first reported a case of fetal varicella syndrome in 1947. Retrospective studies have suggested a 15% to 20% incidence of fetal varicella syndrome after a primary maternal infection. Prospective studies have suggested an attack rate of 4%.^{1, 10}

Prenatal detection of varicella infection has been described. In one report, cordocentesis was used in a 32-week hydrocephalic fetus to detect varicella zoster virus—specific immune globulins.⁴ A second recently presented case described ultrasonographic findings at 30 weeks' gestation compatible with fetal varicella syndrome with intrauterine growth retardation and hydramnios, developing after maternal varicella at 15 weeks.³

In utero infections may arise as a result of hematogenous spread, ascending infection, or even direct extension. ^{10, 11} Decidua, amniotic fluid, secundines, and the fetus may all be infected. It is possible for some, all, or none of these compartments to be infected at any given time in the course of illness. The actual sequence of events has clinical relevance as to the timing, frequency, and route of clinical diagnostic procedures. Local defense factors arising from decidua and amniotic fluid, such as cytokines and immune globulins, may act to suppress infection and thus modify the course of illness. The fetus may generate immune globulins at 20 to 24 weeks' gestation. Of note, certain fetuses with

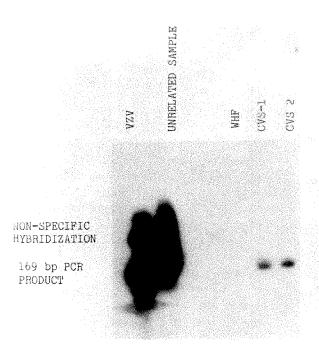

Fig. 2. Southern blot. *Lane 1*, labeled *VZV* (varicella zoster virus), shows 169 bp positive control band. Two bands of higher molecular weight in this lane represent nonspecific hybridization of viral DNA. *Lane 2* contains unrelated sample. Lane *WHF* (whole human fibroblasts) constitutes a negative control. Lanes *CVS 1* and *CVS 2* both contain desired 169 bp fragment of DNA, suggesting that varicella zoster virus DNA was present in both chorionic villus sampling samples.

congenital infections such as rubella have not developed an immunoglobulin M response until 22 to 24 weeks' gestation. The implications, then, for fetal umbilical blood sampling by cordocentesis are that reliable test results may not be available until after 24 weeks, an issue of critical importance for those patients considering termination of pregnancy.

The pathophysiologic characteristics of fetal infections and the variability of clinical expression require further elucidation.^{12, 13} In the case of varicella zoster virus infection the incidence of clinically evident structural defects after fetal infection is not known. Virus may remain latent in ganglia¹⁴ and damage may arise from recurrence.¹⁵ Also unknown are the long-term consequences of infections that do not cause in utero malformations. The analogous situation is the case of in utero cytomegalovirus infection, where neurologic sequelae such as sensorineural hearing loss may develop in structurally normal, but infected, infants.

The current preliminary findings point to molecular tools such as polymerase chain reaction¹⁶ that may prove helpful in extending our understanding of the consequences to the fetus of maternal varicella during pregnancy. Taking care to use concurrent control tissues and to prove the identity of polymerase chain reaction amplification products by Southern blot hybrid-

ization, we proved the presence of varicella zoster virus DNA in two chorionic villus sampling specimens with primer pairs specific to the varicella zoster virus inverted repeat short element containing open reading frame 63 (Fig. 2). The existence of these viral sequences in the tissues documents placental infection but cannot reveal the extent or manifestations of that infection. Furthermore, the mere presence of detectable varicella zoster virus DNA does not indicate continuing viral replication, because truly latent virus is similarly detectable, although the only currently recognized site of varicella zoster virus latency is sensory nerve ganglia and not tissues harvested by chorionic villus sampling. At present, polymerase chain reaction is a promising research tool to investigate the pathophysiologic characteristics of perinatal infections.

Memphis, Tennessee, and Framingham, Massachusetts

A long-sought goal of medical genetics has been development of prenatal diagnostic procedures that do not endanger the conceptus. Reliable and universal screening for cytogenetic disorders would require analysis of fetal cells isolated from the maternal circulation. This would be applicable to all pregnant women, irrespective of their ages or histories. In the current study fetal nucleated erythrocytes were flow sorted on the basis of four parameters: cell size, cell granularity, transferrin receptor, and glycophorin-A cell surface molecule. By polymerase chain reaction with oligonucleotide primers flanking single-copy Y-specific deoxyribonucleic acid sequences, male fetuses were correctly identified among flow-sorted samples in 12 of 12 (100%) pregnancies; female fetuses were correctly identified in 5 of 6 (83%) pregnancies. We also achieved the prenatal diagnosis of fetal aneuploidies by use of flow-sorted nucleated fetal erythrocytes and in situ hybridization with chromosome-specific deoxyribonucleic acid probes: one case of trisomy 21 that was detected in maternal blood taken 1 week after chorionic villus sampling and one case of trisomy 18 that was detected in maternal blood taken immediately before chorionic villus sampling. Although our results are promising, additional data on the background sensitivity and specificity of in situ hybridization in flow-sorted fetal cells will be necessary to minimize subjective interpretation and permit clinical application. (Am J Obstet Gynecol. 1991;165:1731-37.)

Key words: Fetal cells, prenatal diagnosis

A long-sought goal of medical genetics has been development of prenatal diagnostic procedures that do not endanger the conceptus. Amniocentesis and chorionic villus sampling are currently used for recovery of fetal cells for prenatal diagnosis, but these are invasive techniques carrying small, yet finite, risks to the developing fetus. The possibility of noninvasive methods for prenatal diagnosis is especially attractive. This would be applicable to all pregnant women, irrespective of their ages or histories. Indeed, an element of noninvasive screening already exists; concomitant use of maternal age, maternal serum α -fetoprotein, unconjugated estriol level, and human chorionic gonadotropin identifies 60% of pregnancies involving fetal Down

syndrome.¹ Couples determined to be at increased risk are then offered invasive procedures such as amniocentesis. Attempting to delineate ultrasonographic criteria for detecting fetal Down syndrome is another example.²

Reliable and universal screening for cytogenetic disorders would require analysis of fetal cells isolated from the maternal circulation. Indeed, obstetricians and pathologists have long known that occasional fetal cells find their way into the maternal circulation, as indicated by the phenomena of rhesus immunization and amniotic fluid embolization. In 1969 Walknowska et al.³ first proposed recovering fetal cells from maternal blood for prenatal diagnosis.

We sought to determine whether fetal nucleated erythrocytes could be sorted from maternal blood during the first and second trimesters by multiparameter flow cytometry and confirmed this with polymerase chain reaction amplification of oligonucleotide primers flanking single-copy Y-specific deoxyribonucleic acid (DNA) sequences. We also report here the first-trimester prenatal diagnoses of fetal aneuploidy with the use of fetal nucleated erythrocytes that have been flow sorted from maternal blood and analyzed by in situ hybridization with chromosome-specific DNA probes: one case of trisomy 21 that was diagnosed from maternal blood taken 1 week after chorionic villus sam-

pling and one case of trisomy 18 that was diagnosed from maternal blood taken immediately before chorionic villus sampling.

Methods

Specimens and sample preparation. Specimens were taken from volunteers giving informed consent under a University of Tennessee, Memphis, Institutional Review Board—approved protocol. Immediately before chorionic villus sampling or amniocentesis approximately 20 ml venous blood was aspirated into vacuum tubes containing acid-citrate-dextrose solution A. Each blood sample was logged for reference to cytogenetic analysis and coded. Blood samples stayed in the solution for up to 36 hours before preparation and sorting. In one case blood was drawn 1 week after chorionic villus sampling diagnosis of fetal trisomy 21. Umbilical cord blood from term pregnancies served as controls.

Four milliliters of blood diluted 1:1 with phosphate-buffered saline solution was layered over 3 ml of chilled Ficoll-Paque (Pharmacia, Piscataway, N.J.) and centrifuged at 350g for 40 minutes at room temperature. All buoyant mononuclear cells, early reticulocytes, and small numbers of erythrocytes were removed by suction and washed twice with phosphate-buffered saline solution. The yield ranged from 2 to 3×10^7 cells per sample.

After washing, the cells were resuspended in phosphate-buffered saline solution with 2% fetal bovine serum and 0.1% sodium azide (buffer). The cells were counted and the volume adjusted to a concentration of 5×10^6 cells per milliliter. Cells were dual labeled for 30 minutes at 4° C with transferrin receptor monoclonal antibody conjugated to fluorescein isothiocyanate (T9-

FITC, Coulter Immunology, Hialeah, Fla.) and glycophorin-A monoclonal antibody conjugated to phycoerythrin (KC16-Rd¹, Coulter Immunology). The final concentration was $0.2~\mu g$ per 1 million cells for each antibody. Labeled cells were washed once, resuspended at 10^7 cells per milliliter in buffer, and analyzed and sorted by flow cytometry (as described).

Flow cytometry. Cells were sorted with an EPICS Elite flow cytometer (Coulter Cytometry, Hialeah) with standard instrument computer and electronics. The unit was configured with an air-cooled 15 mW argon laser (model 2201, Cyonics, San Jose, Calif.) emitting at 488 nm. Elite 2.1 cytometry software was used. Cells were analyzed in a single pass at a rate of 2500 to 5000 cells per second. Positive selection was based on forward scatter (cell size), side scatter (cell granularity), green fluorescence (transferrin receptor, T9-FITC), and orange fluorescence (glycophorin-A, KC16-Rd¹). Sort gates for positive cell selection are shown in Fig. 1. Dual fluorescent cells of appropriate size and granularity were sorted directly into a 1.5 ml Eppendorf tube containing 1 ml of buffer.

Polymerase chain reaction. For polymerase chain reaction sorted fetal cells were centrifuged at 10,000g for 3 minutes and the buffer removed. Tubes containing the cells were stored frozen at -85° C pending batch analysis. We used the dual-amplification ("nested primer") polymerase chain reaction method described by Lo et al.⁴ with oligonucleotide primers flanking a single-copy Y-chromosome-specific DNA sequence. The final product was run in 4% agarose gel and stained with ethidium bromide for visualization and scoring. For details of the procedure, see Wachtel et al.⁵

In situ hybridization. The concentration of sorted

fetal cells was adjusted to 4000 to 12,000 nuceli per milliliter of phosphate-buffered saline solution containing 5% fetal bovine serum and 0.1% azide. For each slide 1000 to 3000 nuclei were plated onto poly-L-lysine-coated slides by cytocentrifugation at 550 rpm for 8 minutes (Cytospin, Shanndon, Pittsburgh). Slides were air dried, fixed by immersion in acid ethanol (containing 5% glacial acetic) for 10 minutes at room temperature, and stored dry with a desiccant at 4° C for batch processing. Immediately before hybridization, the cells were rehydrated by two washes in phosphatebuffered saline solution for 2 minutes at room temperature. All remaining washes and incubations were accomplished at room temperature unless otherwise noted.

Cells on the slides were permeabilized in phosphatebuffered saline solution with 0.05% Triton X-100 for 3 minutes, washed twice for 2 minutes with phosphatebuffered saline solution, treated with 0.1 N hydrochloric acid for 10 minutes, and again washed twice for 2 minutes with phosphate-buffered saline solution. Each slide was treated with 25 µl of 50 ng/ml proteinase K in 20 mmol/L Tris hydrochloride, pH 7.0, coverslipped, and deproteinized for 7 minutes at 37° C. Digestion was stopped by two 2-minute washes in phosphate-buffered saline solution containing 2 mg/ml glycine. Samples were fixed for 5 minutes with 4% paraformaldehyde, washed twice for 2 minutes in phosphate-buffered saline solution, and blocked for 10 minutes with 0.25% acetic anhydride in 0.1 mmol/L triethanolamine hydrochloride containing 0.9% sodium chloride, pH 8.0. The cells were dehydrated by treatment with a series of 70%, 80%, 90%, and 100% ethanol solutions (1 minute per solution), and air dried for hybridization.

In situ hybridizations were performed with chromosome-specific probes (Integrated Genetics, Inc., Framingham, Mass.): HL 10-10-8a, a repetitive sequence specific for the X centromere; pWe7.1 and pWe5.0, overlapping mid-long-arm regions specific for chromosome 18; and 519, a 20 kb sequence on the distal long arm of chromosome 21; pDP97, a 40 kb repeat sequence from the distal long arm of the Y chromosome, was provided by David Page, Cambridge, Mass. For each hybridization, probe was combined with 50 ng biotinylated cosmid DNA, 1 µg competitor human DNA (except for the Y probe), and 8.95 µg salmon sperm DNA (9.95 µg with the Y probe). Probe, competitor, and carrier DNA were precipitated with 100% ethanol, pelleted, washed with 70% ethanol, and dried in a Speed-Vac (Savant, Hicksville, N.Y.) for 5 to 15 minutes.

The sample was resuspended at a final concentration of 10 µg total DNA per 10 µl of hybridization solution consisting of 50% formamide and 10% dextran sulfate in 6× saline-sodium citrate buffer (SSC). Ten microliters of probe was placed on the sample spot; this was overlaid with a glass coverslip and sealed with rubber cement. Sample and probe DNA was denatured on a slide warmer for 7 minutes at 80° C and hybridized overnight in a moist chamber at 37° C. Each slide was washed three times for 5 minutes with 50% formamide in $0.1 \times$ SSC at 42° C, once for 5 minutes in $2 \times$ SSC at room temperature, and three times for 5 minutes in 2× SSC at 60° C. The samples were blocked with 50 μ l of 4 × SSC with 3% bovine serum albumin at 37° C for 30 minutes in a moist chamber. Cells were stained with 50 µl of 5 µg/ml avidin-fluorescein isothiocyanate in $4 \times$ SSC with 1% bovine serum albumin-0.1% Tween 20. The slides were incubated in the dark for 15 minutes at 37° C in a moist chamber, washed once for 5 minutes in 2× SSC at room temperature, and drained. Next, the slides were mounted with 20 μl of antifade-4',6-diamidino-2-phenylindole, coverslipped, and sealed with nail polish. Slides were stored at 4° C in the dark for scoring by fluorescence microscopy.

Results

Flow cytometry. Among the control umbilical cord samples sorted (n = 17), cells positive for each of the four parameters accounted for a value of $21.0\% \pm 7.6\%$ (mean \pm SD) of the mononuclear cell fraction separated over Ficoll. By contrast, cells positive for the four parameters represented only $0.4\% \pm 0.7\%$ (mean ± SD) of cells separated from first-trimester maternal samples (n = 50) and 2.2% \pm 3.6% (mean \pm SD) of cells sorted from second-trimester maternal samples (n = 20). Although many of the sorted cells were anucleate reticulocytes, we could generally retrieve 2000 to 20,000 nuclei, of which an estimated 10% were nucleated fetal erythrocytes. Thus we predicted that fetal cells should be present in frequencies of about one nucleated erythrocyte per 107to 108 maternal cells in maternal whole blood.

Polymerase chain reaction. We tested 18 sorted patient blood samples by polymerase chain reaction. Male fetuses were correctly identified in 12 of 12 (100%) pregnancies, whereas female fetuses were correctly identified in 5 of 6 (83%) pregnancies. The overall efficiency of fetal sex identification with polymerase chain reaction was thus 17 of 18 (94%) among sorted samples.

In situ hybridization. The background signal level of Y-specific probe (pDP97) was 5% in sorted female cord blood samples (Fig. 2). With 5% used as a baseline above which male sex would be predicted, fetal sex was correctly identified in 68% of samples sorted from maternal peripheral blood (6/8 females and 9/14 males).

Cases involving fetal aneuploidy. In the first case a 37-year-old patient underwent transcervical chorionic

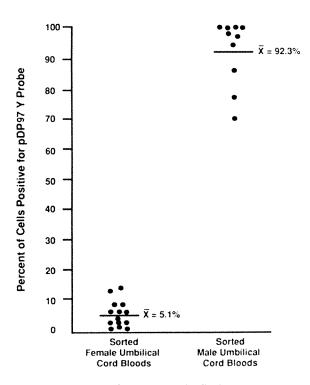

Fig. 2. Distributions of percentage of cells showing positive in situ hybridization signal with pDP97 Y-chromosome-specific DNA probe in sorted umbilical cord blood samples from female (n = 14) and male (n = 10) infants.

villus sampling at 10 weeks' gestation. Her one previous pregnancy resulted in the delivery of a normal male infant. Cytogenetic analysis revealed a 47,XX,+21 karyotype (direct cytotrophoblasts). One week after chorionic villus sampling, a maternal blood specimen was collected for flow cytometry. After being enriched for fetal cells, the sample was analyzed by in situ hybridization with probe (519), which as previously noted is specific for chromosome 21. Slides were scored by three independent observers who were unaware of the fetal karyotype. Sixty-two nuclei were examined: 13 (21%) displayed the two hybridization signals expected of normal diploid cells, but 24 of 62 (39%) displayed three signals indicating trisomy for chromosome 21 (Table I). The diagnosis of 47,XX,+21 was confirmed in abortus tissue.

In the second case a 42-year-old woman was referred for prenatal diagnosis at 10.8 weeks' gestation because of maternal age. Her three previous pregnancies resulted in the delivery of a normal female infant and the delivery of a set of normal twins, one male and one female. From a sample received before chorionic villus sampling, flow-sorted fetal cells were analyzed by in situ hybridization with probes of chromosomes, Y, X, 18, and 21 (Fig. 3). Again, samples were scored without knowledge of fetal karyotype. Results are shown in Table II: Y probe, 8.7% of the nuclei exhibited a single

hybridization signal and 90.3% exhibited no signal; X probe, 14.5% of the nuclei displayed a single hybridization signal and 86% two signals; chromosome 18 probe, 8.5% of the nuclei displayed three hybridization signals; chromosome 21 probe, 95.2% of the nuclei showed two hybridization signals. In aggregate, these data indicate a male fetus with trisomy 18. The patient elected to terminate the pregnancy on the basis of the chorionic villus sampling results, and the diagnosis of 47,XY, +18 was confirmed in the abortus tissue.

Comment

In the current study fetal nucleated erythrocytes were flow sorted on the basis of four parameters: cell size, cell granularity, transferrin receptor, and glycophorin-A. By polymerase chain reaction with oligonucleotide primers flanking single-copy Y-specific DNA sequences, male fetuses were correctly identified among flow-sorted samples in 12 of 12 (100%) pregnancies and female fetuses were correctly identified in 5 of 6 (83%) pregnancies. The estimated ratio of fetal nucleated erythrocytes to maternal cells was 1:107 to 1:108. Multiparameter flow cytometry enabled sorting enrichment of approximately one fetal nucleated erythrocyte per 10 to 20 nucleated maternal cells. With flowsorted cells and in situ hybridization with a Y-chromosome-specific DNA probe, fetal sex was correctly predicted in 15 of 22 (68%) pregnancies.

Our findings help confirm the possibility of recovering fetal cells from maternal blood for prenatal diagnosis, a thesis first raised in 1969 by Walknowska et al.3 These workers described XY metaphases in maternal blood of pregnant women carrying a male fetus. Although subsequent reports suggested that fetal cells could be detected and isolated from maternal blood, 6-8 skepticism remained. More recently, however, several groups have made significant advances. Lo et al.4.9 studied unsorted blood from pregnant women. Polymerase chain reaction was performed, with nested primers used for a Y sequence. Women carrying a male fetus proved far more likely to show a hybridization signal than those carrying a female fetus. Concurrently, Mueller et al.,10 using a different approach, screened 6000 monoclonal antibodies generated from placental tissue; five were found to be specific for fetal tissue. After these monoclonal antibodies were exposed to maternal blood from pregnant women, isolated cells were subjected to polymerase chain reaction for Y sequences. Fetal sex was correctly identified in seven of seven males and six of seven females. Bianchi et al.11 flow sorted on the basis of transferrin-receptor-positive cells and used polymerase chain reaction to amplify for Y sequences. Of eight samples showing the Y sequence, six were from pregnancies in which women were carrying male fetuses. Finally, Yeoh et al.12 sorted fetal cells for a pa-

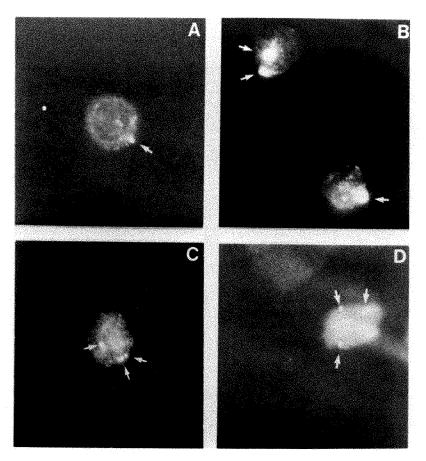

Fig. 3. Flow-sorted cells hybridized to various chromosome-specific probes. Probes were labeled with biotin and visualized with fluorescein isothiocyanate-streptavidin. All cells were from a single blood sample and analyzed in coded fashion. A, Male cell of fetal origin. Fluorescent signal (arrow) in cell hybridized to pDP97 probe, which identifies repetitive sequence in heterochromatic region on long arm of Y chromosome. B, Female cell of maternal origin (upper left) showing two signals (two arrows) and male cell of fetal origin (lower right) showing single signal (arrow). Cells hybridized to X-chromosome-specific cosmid probe, which identifies pericentromeric repeat sequence on X chromosome. C and D, Trisomy 18 fetal cells sorted from maternal blood. Fluorescent signals (three arrows) in cells hybridized to chromosome 18-specific cosmid contig probe, which identifies single-copy sequence on distal long arm of chromosome 18.

Table I. Flow-sorted maternal blood specimen obtained after transcervical chorionic villus sampling in woman carrying 47,XX, +21 fetus: Distribution of in situ hybridization signals for chromosome 21specific probe (519)

			No. of hybridization si	gnals per nucleus		
	0	1	2	3	4	Total

ternal HLA allele not present in the mother, subjected sorted cells to polymerase chain reaction for a Y sequence, and again found encouraging results with respect to predicting fetal sex. These studies suggest that fetal cells indeed exist in maternal blood. However, polymerase chain reaction will rarely be diagnostic; instead, other technologies will be necessary for this

To this end, this is the first demonstration of prenatal

detection of fetal aneuploidies by use of flow-sorted nucleated fetal erythrocytes and chromosome-specific DNA probes. In one case in which a blood sample was obtained 1 week after transcervical chorionic villus sampling, 24 of 62 (38.7%) cells showed three hybridization signals with a chromosome 21-specific DNA probe; this indicated fetal trisomy 21. We have previously shown that fetal cells are usually transferred to maternal circulation as result of chorionic villus sampling,13 and we

Table II. Flow-sorted maternal blood specimen obtained before transabdominal chorionic villus sampling in woman carrying 47,XY, +18 fetus: Distribution of in situ hybridization signals for chromosome-specific probes—Y chromosome (pDP97), X chromosome (HL10-10-8a), chromosome 18 (pWe7.1 and pWe5.0), and chromosome 21 (519)

		No. of hyb	ridization signals per nucle	us

suspect that the large number of trisomic cells in this case represents such a transfer. That 8 of 62 nuclei (12.9%) showed four signals with the 21-specific probe could indicate either tetrasomy reflecting transfer of multinucleated trophoblast cells or, alternatively, inclusion of dividing maternal or fetal cells in the sorted population. Other potential variables are discussed in the text that follows. In the second and more noteworthy case, a blood sample was taken before chorionic villus sampling. The combination of results from X and Y probes indicated that approximately 10% of the sorted cells were from a male fetus, the remaining 90% of cells being of maternal origin. Approximately 9% of sorted cells showed three hybridization signals with the chromosome 18-specific DNA probe. In aggregate, these data indicate a male fetus with trisomy 18. In both cases the chromosome abnormalities were confirmed in the abortus specimens.

A variety of factors have been shown to influence hybridization efficiency and signal specificity.14.15 Hybridization or detection efficiency, in particular, has an impact on the enumeration of interphase chromosomes, as does the geometry or chromosomal location within the nucleus. Thus in any population of disomic cells, whereas the majority (≥90%) of cells display two hybridization signals per chromosome, a small number display one, three, or four signals. A single signal most likely results from incomplete detection of both chromosomes because of inefficient hybridization-detection or overlap in the nucleus of the two chromosomal domains. Four hybridization signals arise from G2 nuclei, with three-signal nuclei representing incomplete detection of all four copies of the chromosome.14 Similar effects on detection of chromosomes are seen in trisomic cells and probably account for the detection of four-signal nuclei in case 1 above. The microscopic resolution of contiguous signals and focal planes of a signal that is unclear in one plane may become clear on refocusing the microscope and vice versa. Other variables include (1) the cell type being analyzed, (2) the specific probe used, and (3) the conditions under which the cells are manipulated (e.g., flow sorted). It has been shown that minor alterations in protocol can significantly influence both the qualitative and quantitative aspects of intranuclear trisomy detection. ¹⁴ Protocols must be optimized for each cell type. ¹⁶ A systematic study of the variables with the use of the flow-sorted fetal cells is under way in our laboratories to determine the sensitivity and specificity of in situ hybridization for identification of chromosomal abnormalities in flow-sorted fetal cells.

In summary, our preliminary in situ hybridization data are encouraging, demonstrating the real possibility for prenatal diagnosis of cytogenetic abnormalities with fetal cells isolated from maternal blood. Although promising, additional data on the background sensitivity and specificity of in situ hybridization in flow-sorted fetal cells will be necessary to minimize subjective interpretation and permit clinical application. If these issues are successfully addressed, we would envision this method being used initially as a screening test with confirmation of abnormal results by conventional invasive techniques such as chorionic villus sampling or amniocentesis. Eventually, fetal cells isolated from maternal blood would be used for definitive fetal diagnosis. Methods such as these would enable a couple to undergo prenatal diagnosis without endangering the fetus and open prenatal diagnosis to all couples irrespective of family history or traditional risk factors such as advanced maternal age.

Absence of hyperinsulinemia in isoimmunized fetuses treated with intravascular transfusion

Michael L. Socol, MD,^a Sharon L. Dooley, MD,^a Judith A. Ney, MD,^a John P. Minogue, DMin,^a Dietra D. Millard, MD,^b and Edward S. Ogata, MD^b Chicago, Illinois

We serially sampled blood from fetuses of five severely isoimmunized pregnancies at the time of each intrauterine intravascular transfusion and at birth. We were unable to demonstrate either an elevation in the plasma insulin/glucose ratio or a relationship between the insulin/glucose ratio and hemoglobin concentration at any time period. Plasma total glutathione concentration, however, decreased dramatically from the initial to the second transfusion (323 \pm 114 to 43 \pm 9 ng/ml; t=-5.06, p<0.01). We speculate that intrauterine transfusion may modify or prevent the previously reported fetal pancreatic β -cell hyperplasia and hyperinsulinemia associated with isoimmunization by decreasing red blood cell hemolysis and thereby circulating glutathione. (AM J OBSTET GYNECOL 1991;165:1737-40.)

Key words: Fetal hyperinsulinemia, isoimmunization, intrauterine transfusion

Isoimmunized fetuses have been reported to be at risk for neonatal hypoglycemia presumably as a secondary effect of hyperinsulinemia developing in utero.^{1, 2} Additionally, hyperreactivity of insulin secre-

tion has been noted in severely affected neonates after exchange transfusion with citrated blood or after an intravenous glucose injection. These clinical observations are supported by the pathologic identification of hyperplasia of the islets of Langerhans in infants who die of erythroblastosis fetalis. 4-6

It has been proposed that the degree of fetal hyperinsulinemia is related to the severity of fetal anemia.^{8,7} One hypothesized mechanism for the fetal hyperinsulinism is an impairment of the effect of circulating insulin by glutathione liberated from hemolysis of red blood cells.^{8,9} Destruction or inactivation of circulating insulin might then lead to compensatory hy-

perplasia of the islets of Langerhans. To investigate the relationship between fetal anemia and hyperinsulinemia, we serially measured fetal insulin, glucose, glutathione, and hemoglobin in fetuses of five severely isoimmunized pregnancies at the time of intrauterine intravascular transfusion and at birth.

Material and methods

Our technique for ultrasonographically guided intrauterine straight transfusion has been described previously. 10 Briefly, the placental insertion of the umbilical cord is identified by sector real-time ultrasonography, after which the abdomen is aseptically prepared before local infiltration with lidocaine. A complete surgical scrub is not performed although the operators wear a cap, mask, and gloves. A 22-gauge, 5-inch disposable spinal needle is then guided toward the umbilical cord (preferably the umbilical vein at the placental insertion site) with a 5 MHz sector transducer. After blood is aspirated for the necessary studies, pancuronium bromide (0.05 to 0.1 mg/kg) is infused to paralyze the fetus. Throughout the transfusion the fetal heart rate is intermittently visualized and patients ≥26 weeks' gestation have an intravenous infusion to respond to a possible nonremediable fetal bradycardia. Neither prophylactic antibiotics nor tocolytic drugs are adminis-

This study was approved by the Northwestern University Institutional Review Board and required <1 ml of additional fetal blood to be aspirated before the beginning of each intrauterine transfusion or from umbilical venous cord blood at birth. A double-antibody radioimmunoassay was used to measure plasma insulin with human insulin as the standard. Plasma total glu-

tathione concentrations were measured with a modified enzymatic microassay.¹² The interassay coefficients of variation were 9% for insulin and 10% for glutathione. Plasma glucose concentrations were determined with an automated analyzer (Beckman II) and hemoglobin was measured in a colorimeter with a cyanmethemoglobin reaction (model ELT-800 hematology analyzer or Coulter Counter).

Linear regression by means of a least-squares method was performed to analyze the relationship between fetal hemoglobin and either plasma insulin or the insulin/glucose ratio. Analysis of variance was used to investigate any trend in the insulin/glucose ratio from the initial transfusion until birth. Comparison of glutathione levels at the first and second intrauterine transfusions was performed by paired t test. Statistical significance for all measures was assumed at the p < 0.05 level.

Results

The sensitizing antigen, timing of each transfusion and birth, and measurements of hemoglobin, glucose, insulin, insulin/glucose ratio, and glutathione for each of the five severely isoimmunized fetuses are listed in Table I. Patient 5 had one additional intrauterine transfusion at 32 weeks' gestation, but insufficient fetal blood was aspirated for research studies. All five patients had a negative screen for gestational diabetes mellitus between 24 and 28 weeks' gestation (plasma blood glucose level <130 mg/dl 1 hour after an oral 50 gm glucose load). Four patients were delivered by cesarean section; three were elective repeat operations but patient 3 was delivered by emergency cesarean section because of a fetal bradycardia during her third intrauterine trans-

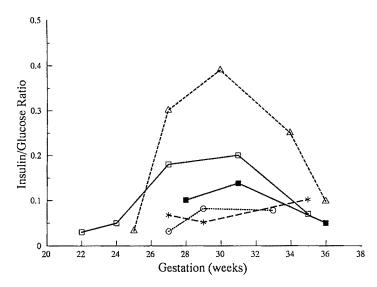

Fig. 1. Insulin/glucose ratios are depicted for each fetus at each intrauterine transfusion. Whether data are analyzed according to first transfusion, second transfusion, and birth or at 26 to 28 weeks, 29 to 31 weeks, and birth, there were no significant differences over time (analysis of variance, p > 0.05).

Table II. Serial measurements (mean \pm SD) obtained for all fetuses (n = 5)

	Glucose	Insulin	Insulin/glucose	Hemoglobin
	(mg/dl)	(µU/ml)	ratio	(gm/dl)
First transfusion	83.4 ± 14.3	4.2 ± 1.7	0.05 ± 0.03	6.0 ± 1.5
Second transfusion	96.2 ± 33.3	13.6 ± 13.2	0.13 ± 0.10	9.2 ± 2.0
Birth	80.2 ± 16.0	6.5 ± 2.2	0.08 ± 0.02	9.3 ± 1.3

fusion. The pretransfusion fetal blood sample in this case was taken before fetal compromise and was used for the birth measurements. The range of birth weight was 2020 to 2925 gm. Four of the neonates had an Appar score of >7 at 5 minutes; that neonate who was delivered by emergency cesarean section had a score

The measurements (mean ± SD) obtained before the initial transfusion, before the second transfusion, and at birth are displayed in Table II. Although fetal transfusions were performed at differing gestational ages for the five pregnancies studied, each fetus was transfused at 26 to 28 weeks and again at 29 to 31 weeks. Mean values at 26 to 28 weeks for plasma insulin and the insulin/glucose ratio were 15.5 \pm 13.8 μ U/ml and 0.14 ± 0.10 ; at 29 to 31 weeks these were 18.0 ± 14.5 μ U/ml and 0.17 \pm 0.12, respectively.

There were no identifiable relationships between fetal hemoglobin and either plasma insulin or the insulin/glucose ratio at any time period. The insulin/glucose ratios are depicted for each fetus at each transfusion and at birth in Fig. 1 (analysis of variance, p > 0.05 for first transfusion, second transfusion, and birth, or at 26 to 28 weeks, 29 to 31 weeks, and birth).

Plasma total glutathione concentrations were mea-

sured only at the initial and second intrauterine transfusions because after this time the fetal blood volume has essentially been replaced by adult red blood cells. There was a significant decline (mean \pm 1 SD) from 323 ± 114 to 43 ± 9 ng/ml (t = -5.06, p < 0.01).

Comment

Reports in the late 1960s alerted pediatricians to the propensity for hypoglycemia to develop in neonates of isoimmunized pregnancies.1,2 Analogies were drawn to the infant of the diabetic mother because hyperplasia of the islets of Langerhans and increased extractable pancreatic insulin were documented in newborns dying of erythroblastosis fetalis.4-6,8 Additionally, elevated plasma insulin levels were observed shortly after birth3.7,13 and were noted by some authors to be inversely correlated with hemoglobin concentration, particularly in the most severely affected pregnancies.3.7

In our five severely isoimmunized pregnancies requiring intrauterine intravascular transfusions neither fetal plasma insulin levels nor the insulin/glucose ratio was related to hemoglobin concentration at any time period. At first glance fetal hyperinsulinemia was suggested because the mean plasma insulin values at 26 to 28 weeks and 29 to 31 weeks, but not at birth, approached¹⁴ or exceeded¹⁵ the upper limit of previously published 95% confidence intervals derived in utero from a population of appropriate-for-gestationalage fetuses. Our fetal insulin measurements, however, may reflect higher fetal glucose concentrations that are secondary effects of the precautionary maternal intravenous infusion that was started in case of fetal complications from the intrauterine transfusion. In contrast to insulin, mean insulin/glucose ratios at 26 to 28 weeks, 29 to 31 weeks, and birth were not elevated and the individual insulin/glucose ratios are distributed around the mean values reported at comparable gestational ages.¹⁴

It is possible that our limited number of patients precluded the identification of fetal hyperinsulinemia. The clinical observation in diabetic pregnancies of accelerated fetal somatic growth in the late second trimester suggests that the fetal pancreas is capable of increased insulin secretion by this time period.16 Alternatively, fetal hyperinsulinemia may not occur as commonly in isoimmunized pregnancies as previously reported. A third possibility, however, is that in utero treatment relatively early in gestation may modify or prevent pancreatic β-cell hyperplasia and hyperinsulinemia. Consistent with this premise is the dramatic decrease in fetal glutathione concentration observed by the time of the second intrauterine transfusion. Furthermore, there was a suggestion of a rise in insulin/glucose ratio by the second transfusion with a subsequent decline by birth, possibly depicting the interruption of a pathophysiologic sequence. Replacement of fetal blood with compatible adult cells decreases hemolysis and thereby circulating glutathione. If islet cell hyperplasia is a secondary result of peripheral destruction or inactivation of insulin by glutathione, this process may be ameliorated by intrauterine transfusion.

Does the brachial artery doppler flow velocity waveform reflect changes in downstream impedance?

Fiona M. Fairlie, MRCOG, and James J. Walker, MD

Glasgow, Scotland

Brachial artery Doppler flow velocity waveforms were recorded from 10 nonpregnant women and 19 women with uncomplicated pregnancies. The pregnant group showed higher peak systolic frequencies (3.24 compared with 2.26, p=0.01), higher maximum end-diastolic frequencies (0.62 compared with 0.25, p=0.01), and lower pulsatility indices (2.57 compared with 3.95, p=0.06) when compared with the nonpregnant group. These Doppler changes could reflect the increase in maternal cardiac output and decline in systemic vascular resistance that occur in normal pregnancy. The effect on brachial artery Doppler of acutely increasing downstream impedance by hand immersion in ice-cold water was studied in nine women with uncomplicated pregnancies at 32 to 38 weeks' gestation. Immersion for 15 seconds was associated with a significant reduction in peak systolic frequencies (from 3.06 to 1.97, $p \le 0.005$) and maximum end-diastolic frequencies (from 0.82 to 0.03, $p \le 0.005$) and a significant increase in the pulsatility index (from 1.87 to 5.62, $p \le 0.005$). These changes persisted for the duration of immersion (60 seconds). After immersion, the brachial artery flow velocity waveform returned to its preimmersion pattern by 60 seconds. We conclude that in normal pregnancy, the maternal brachial artery Doppler flow velocity waveform reflects acute and chronic changes in downstream impedance. (AM J OBSTET GYNECOL 1991;165:1741-4.)

Key words: Brachial artery Doppler, downstream impedance

The Doppler flow velocity pattern in vivo is influenced by a number of physiologic factors. It is generally accepted that cardiac output is an important determinant of peak systolic frequencies, whereas maximum end-diastolic frequencies are influenced by downstream impedance. Arteries feeding vascular beds of high resistance are associated with little or no end-diastolic frequencies, whereas the Doppler flow velocity waveform recorded from a low-resistance bed remains above the baseline throughout diastole.

Many complications of pregnancy are associated with abnormal maternal and fetal hemodynamics. Doppler ultrasonography is a noninvasive method of measuring changes in blood flow velocity. To date, obstetric Doppler studies have concentrated on the fetal and uteroplacental circulations. The possibility of studying Doppler blood flow changes in the maternal peripheral vascular system in pregnancy has received scant attention.

The purpose of this study was to investigate Doppler blood flow changes in the maternal brachial artery during normal pregnancy and the effect on the brachial artery flow velocity waveform of an acute increase in downstream impedance.

Methods

The effect of normal pregnancy on the maternal brachial artery Doppler waveform pattern. Brachial artery Doppler flow velocity waveforms were recorded from 10 healthy, nonpregnant women and 19 pregnant women. The pregnant group consisted of nine women with uncomplicated pregnancies between 8 and 13 weeks' gestation and 10 women with uncomplicated pregnancies between 32 and 38 weeks' gestation. Doppler recordings were obtained from the right brachial artery as it traversed the brachial fossa. Women were positioned in a semirecumbent position and allowed to rest for 15 minutes before Doppler recordings were obtained. Flow velocity waveforms were recorded with a Vasoflo 3 continuous-wave Doppler scanner with a 4 MHz probe and a 100 Hz wall filter. Doppler recordings were obtained by the same operator. The angle between the Doppler probe and the skin of the brachial fossa was adjusted until arterial Doppler waveforms with a clearly defined maximum velocity profile were obtained without interference from brachial venous Doppler signals.

To study the variability of the brachial artery Doppler flow velocity waveform with time, flow velocity waveforms were recorded for a period of 10 seconds every minute for 5 consecutive minutes. At each recording period, five Doppler flow velocity waveforms were quantified by measuring peak systolic frequency, maximum end-diastolic frequency, and pulsatility index.⁴ The Doppler measurements and maternal heart rate

were automatically calculated by the Vasoflo 3 spectrum analyzer. Mean values of peak systolic frequency, end-diastolic frequency, pulsatility index, and heart rate for the five waveforms were calculated. Average values for the 5 minutes studied were then calculated together with a coefficient of variation. Brachial artery Doppler peak systolic frequency, end-diastolic frequency, pulsatility index, and maternal heart rate for the non-pregnant group were compared with values obtained from the pregnant women.

The effect of an acute increase in downstream impedance on the maternal brachial artery Doppler flow velocity waveform in normal pregnancy. The effect of an acute increase in downstream impedance on the maternal brachial artery flow velocity waveform was studied in nine women with uncomplicated pregnancies at a gestational age between 32 and 38 weeks. Subjects were positioned in a semirecumbent position, and, after a 15-minute rest period, the right brachial artery Doppler flow velocity waveform was recorded for 5 seconds. The subject's right hand and wrist were then immersed in ice-cold water for 60 seconds. Brachial artery flow velocity waveforms were recorded for 5 seconds at intervals of 15, 30, and 60 seconds during immersion and at 30 and 60 seconds immediately after immersion. For each recording period five flow velocity waveforms were analyzed, and mean values for peak systolic frequency, end-diastolic frequency, pulsatility index, and maternal heart rate were calculated.

The use of continuous-wave Doppler ultrasonography to study brachial artery blood flow changes in preg-

nancy had been approved by the University of Glasgow ethical committee, and all patients recruited to the study gave informed consent. Student t test and Wilcoxon signed rank test were used for statistical analysis.

Results

Table I shows mean values for brachial artery peak systolic frequency, end-diastolic frequency, pulsatility index, and maternal heart rate in the three patient groups (i.e., nonpregnant, first trimester of pregnancy, and third trimester of pregnancy). Women in the first trimester of pregnancy showed significantly higher peak systolic frequencies (p = 0.01), compared with those of the nonpregnant group. Brachial artery maximum end-diastolic frequencies were significantly higher in women in the third trimester of pregnancy than in either the first-trimester group (p < 0.005) or the nonpregnant group (p = 0.01). Pulsatility index was significantly lower in the third-trimester group than in the first-trimester group (p < 0.005). Pulsatility index in the nonpregnant group was similar to that of the first-trimester group but showed higher values (not statistically significant, p = 0.06) when compared with the third-trimester group. Women in the third trimester of pregnancy had a significantly higher heart rate compared with that of the other two study groups (p < 0.05).

Table II shows the coefficients of variation for brachial artery peak systolic frequency, end-diastolic frequency, pulsatility index, and maternal heart rate for the three groups compared in Table I. Maximum end-diastolic frequencies showed the highest coefficients of variation, and maternal heart rate showed the lowest coefficients of variation. Statistical differences were present in the coefficients of variation for peak systolic frequencies (first trimester compared with third trimes-

ter, p = 0.03) and pulsatility index (nonpregnant compared with third trimester, p < 0.01).

Table III shows the changes in brachial artery peak systolic frequency, end-diastolic frequency, pulsatility index, and maternal heart rate during cold water immersion of the hand and wrist during the third trimester of pregnancy. Cold water immersion for 15 seconds was associated with a significant fall in brachial artery peak systolic frequencies and maximum end-diastolic frequencies ($p \le 0.005$) and a significant rise in the pulsatility index (p < 0.005). These changes were maintained during the 60 seconds of immersion. After immersion, brachial artery peak systolic frequencies and maximum end-diastolic frequencies increased and the pulsatility index fell significantly ($p \le 0.01$). By 60 seconds after immersion, brachial artery Doppler parameters had returned to their preimmersion values. Maternal heart rate rose during cold water immersion and fell after immersion. Heart rate changes reached statistical significance only when readings at 60 seconds of immersion were compared with readings 30 seconds after immersion (p = 0.02).

Comment

The Doppler flow velocity waveform pattern can be defined by measuring maximum velocity signals, i.e., the envelope of the Doppler spectrum. Waveform indexes dependent on peak systolic frequencies and maximum end-diastolic frequencies have been derived as a semiquantitative method of measuring Doppler waveform changes. The pulsatility index4 is one such index. These indices are thought to be independent of the angle of insonation. Analysis of waveform indices does not provide a measure of a change in flow rate, but it can suggest a possible mechanism. In arterial Doppler flow velocity waveforms, it is thought that cardiac output is an important determinant of peak systolic frequencies, whereas end-diastolic frequencies reflect downstream impedance. The purpose of our study was to test this theory in vivo.

Normal pregnancy is associated with significant hemodynamic changes in the maternal circulation. The timing and magnitude of these changes have been studied with invasive techniques^{5,6} and more recently by the noninvasive method of Doppler ultrasonography.7.8 There is general agreement that cardiac output increases by 30% to 50% during pregnancy. Cardiac output is a function of stroke volume and heart rate. In early pregnancy the increase in cardiac output appears to be mainly due to an increase in stroke volume, whereas in later pregnancy increased cardiac output is more dependent on a rise in maternal heart rate.9 Systemic vascular resistance, which is directly proportional to mean arterial pressure and inversely proportional to cardiac output, decreases during pregnancy. It has been suggested that this fall observed in normal pregnancy is related to decreased vascular resistance in the uteroplacental and pulmonary circulation.10

In the first part of our study we investigated the effect of pregnancy on the brachial artery flow velocity waveform pattern. In the first trimester peak systolic frequencies increased significantly. This change is compatible with the increase in maternal cardiac output normally seen in early pregnancy. Brachial artery Doppler flow velocity waveforms from women in the third trimester showed significantly higher end-diastolic frequencies compared with women in the first trimester and nonpregnant women. This change would be consistent with the fall in peripheral vascular resistance observed in normal pregnancy. We recognize that peak systolic frequencies and end-diastolic frequencies are dependent on the angle of insonation of the ultrasonographic beam. In our study with continuous-wave Doppler the magnitude of this angle was unknown. In spite of this source of variation, the changes we observed were statistically significant, and we suggest that they cannot be dismissed as due to chance. Pulsatility index is a function of peak systolic and end-diastolic frequencies and is thought to be independent of the angle of insonation. Brachial artery pulsatility index

 $[\]dagger p \leq 0.01$, Wilcoxon test for paired data, 30 seconds after immersion compared with 60 seconds' immersion.

 $[\]ddagger p \le 0.01$, Wilcoxon test for paired data, 60 seconds after immersion compared with 30 seconds after immersion.

p = 0.02, Wilcoxon test for paired data, 30 seconds after immersion compared with 60 seconds' immersion.

was significantly lower in the third-trimester group than in the first-trimester and nonpregnant groups. The fall in pulsatility index may be partly explained by the increase in maternal heart rate in the third trimester (a characteristic of normal pregnancy). However, the relationship between pulsatility index and heart rate is weak¹¹ and it is more likely that the fall in pulsatility index is a consequence of the increase in end-disatolic frequencies. It would thus appear from our study that changes in the brachial artery Doppler flow velocity waveform pattern occurred during normal pregnancy and appear to follow the expected changes in maternal cardiac output and peripheral resistance.

The variation in the brachial artery flow velocity waveform pattern with time is interesting. Previous studies of brachial artery Doppler velocimetry^{12, 13} do not remark on short-term variability. In our study the same observer performed all the Doppler recordings. The coefficients of variation for brachial artery peak systolic frequency, end-diastolic frequency, and pulsatility index ranged between 20% and 80%. In spite of this variation (particularly evident in end-diastolic frequency), a baseline pattern could be established if the vessel was insonated for a period of 5 minutes and mean values calculated. Furthermore, with this technique of analysis, significant differences in baseline measurements were found between nonpregnant women and pregnant women in the first and third trimesters of pregnancy. This would suggest that, providing a baseline Doppler pattern is established over several minutes, the brachial artery Doppler flow velocity waveform has potential as a clinical tool to study maternal cardiovascular changes.

The effect of acutely increasing downstream impedance on the brachial artery flow velocity waveform was tested by immersing the hand and wrist in ice-cold water. Brachial artery end-diastolic frequencies fell significantly by 15 seconds of immersion. During immersion (a time period of 60 seconds), end-diastolic frequencies showed no change after the 15-second recording. After immersion end-diastolic frequencies increased to reach their preimmersion range by 60 seconds. This response supports an inverse relationship

between end-diastolic frequencies in the brachial Doppler flow velocity waveform and downstream impedance.

Our findings suggest that brachial artery Doppler velocimetry may be a simple, noninvasive method of studying changes in the maternal circulation, in particular changes in peripheral vascular resistance. We postulate that this method could provide information about changes in vascular resistance in pregnancies complicated by maternal hypertension.

Effect of pregnancy on the accuracy of light-reflection rheography

John R. Allbert, MD, William E. Roberts, MD, L. Wayne Hess, MD, and John C. Morrison, MD

Jackson, Mississippi

Light-reflection rheography is a noninvasive method to detect venous obstruction by indirectly measuring venous emptying time. In nonpregnant women it has >90% sensitivity when compared with venography but has not been tested during gestation. To determine if the nonthrombotic occlusion of venous outflow by the pregnant uterus might alter the performance of light-reflection rheography, we examined 17 normal patients with a vascular Accuscan (Hemodynamics, Inc., Boca Raton, Fla.) in the third trimester of pregnancy and 11 patients during the early second trimester. These results were compared with the defined normal (nonpregnant) rate of venous emptying (slope 0.54 ± 0.06). The mean (\pm SD) for the entire sample was 0.58 ± 0.23 mm/sec in the right leg and 0.52 ± 0.19 mm/sec in the left leg measured in the standard sitting position (p = 0.21). The results did not vary with gestational age. A subset of patients in late pregnancy were used to compare the effect of various positions (supine, lateral decubitus, and sitting) on test performance. Positions other than sitting provided results that were inconsistent. It appears that the large pregnant uterus does not significantly obstruct venous outflow from the lower extremities in the standard sitting position; thus the results of light-reflection rheography are not affected. Comparison of light-reflection rheography versus venography in pregnant patients with suspected venous thrombosis is being investigated. (AM J OBSTET GYNECOL 1991;165:1745-7.)

Key words: Deep venous thrombosis, light reflection rheography

Thrombosis is six times more frequent during gestation compared with the incidence in nonpregnant patients. Deep venous thrombosis of the lower extremities complicates approximately 0.018% to 0.29% of pregnancies.1,2 Thromboembolic disease is one of the leading causes of nonobstetric death and, if untreated, will lead to a pulmonary embolus as often as 24%, with a mortality rate of $\geq 15\%$. Unfortunately, the signs and symptoms of deep venous thrombosis (muscle pain, tenderness to palpation, swelling, etc.) are often noted during normal pregnancy when there is no vascular obstruction. Noninvasive tests such as impedance plethysmography and Doppler ultrasonography can be used to diagnose a deep venous thrombosis but require welltrained and experienced personnel. Venography has been considered the gold standard for diagnosis of venous thrombosis, but it is invasive, it is associated with a significant amount of morbidity, and up to 45% of patients with suspected deep venous thrombosis will have a normal venogram.4

Light-reflection rheography is a noninvasive method using light emitting diodes and a sensor to measure light reflected from the skin surface. The intensity of the reflected light establishes a graphic pattern that indirectly quantifies parameters of venous function by measuring changes in microcirculation. Light-reflection rheography has been shown to be as accurate as other noninvasive tests in the diagnosis of deep thrombosis in nonpregnant patients.5,6 Because the gravid uterus may decrease the venous outflow from the lower extremities, the usefulness of light-reflection rheography in the pregnant patient is questionable. The purpose of this study was to determine if light-reflection rheography during gestation would perform as consistently as had been demonstrated in patients who were not pregnant.

Material and methods

In this prospective study patients in the second and third trimesters were evaluated by light-reflection rheography during a prenatal visit. Inclusion criteria were (1) intrauterine pregnancy >12 weeks' gestation, (2) no symptoms or physical signs consistent with deep venous thrombosis or superficial thrombophlebitis, and (3) no previous history of deep venous thrombosis, superficial thrombophlebitis, or venous insufficiency. After informed consent was obtained, the light-reflection rheography measurements were carried out. A total of 28 patients with uncomplicated pregnancies were ex-

amined, 11 at 13 to 27 weeks' gestation and 17 between 28 and 42 weeks.

Measurements were taken with the patient seated comfortably in the chair with both feet flat on the floor, as for nonpregnant subjects. Pedal pulses were examined to rule out arterial occlusive disease. The light-reflection rheography sensor head was attached to the leg to be tested 10 cm above the medial malleolus. The patient was instructed to dorsiflex the foot 10 times over 15 seconds. The slope of the venous emptying curve by light-reflection rheography was calculated by the formula:

Slope =
$$\Delta R/T_1$$

where ΔR is venous drainage and T_1 is measured in seconds. The result is the rise of the evacuation curve in millimeters per second (rate of emptying).⁶ A slope of <0.31 mm/sec was used as the value indicating deep venous thrombosis, whereas a normal slope was 0.54 ± 0.06 in nonpregnant subjects.⁵ After the initial examination with the patient in a sitting position, a subset of patients in the third trimester were retested in the lateral decubitus position, the supine position, and a sitting position with a tilt to determine if the results of the tests would be affected by the position of the gravid uterus. A paired t test was used to determine statistical significance. A t value of t0.05 was considered significant.

Results

In the standard sitting position the results were very similar to the previous results in nonpregnant patients. As Table I demonstrates, the average slope in all pregnancies tested was 0.58 ± 0.23 (ISD) for the right leg and 0.52 ± 0.19 (\pm SD) in the left leg (p = 0.21). The false-positive rate with a slope ≤ 0.31 mm/sec was 6% (n = 3).

In a subset of 11 patients in the third trimester other positions were tested to determine if shifting the weight of the uterus from the inferior vena cava would affect the results (Table II). In 11 patients the right leg was tested while a wedge was placed under the right hip to shift the weight to the left side. Four of these patients had abnormal examination results for a false-positive rate of 36%. Thirteen subjects were placed in the semi-Fowler left lateral decubitus position for the same purpose, and four of them had abnormal test results for a false-positive rate of 31%. In the supine position none of the test results revealed a deflection curve at all.

Comment

Acute deep venous thrombosis results in significant increases in morbidity and mortality during pregnancy as a result of pulmonary emboli. Unfortunately, pregnant patients frequently have signs and symptoms consistent with deep venous thrombosis necessitating performance of noninvasive screening tests that have a high false-positive rate and are very operator dependent. Venography is the technique that yields the most accurate information regarding the extent of occlusion and location of thrombosis, but it carries a significant morbidity rate. A noninvasive test for deep venous thrombosis that is sensitive and specific and requires minimal operator skill would be desirable.

Light-reflection rheography appears to fulfill these requirements. It has been shown to be 92% sensitive and 94% specific in previous studies involving non-pregnant patients. ^{5,6} Prior investigations have also demonstrated that false-positive results may occur in elderly patients and subjects with a history of congestive heart failure or leg edema. ⁵ The technique has not been tested in pregnant women. It seems possible that the gravid uterus might affect venous return from the lower extremities and thus increase the false-positive rate of this test.

Before a prospective study comparing venography with light-reflection rheography during pregnancy was begun, it was necessary to determine whether the gravid uterus would obstruct the venous outflow from the lower extremities frequently enough to make light-reflection rheography ineffective in the assessment of patients with a suspected deep venous thrombosis. The standard sitting position that has been used in previous

studies was also the most effective among the pregnant patients in this investigation. Other positions tested did not produce reliable results. The finding of no deflection on light-reflection rheography in the supine position was not surprising in that there is not a column of blood to be affected by gravity as in the other positions. The amount of time required to train our personnel to perform the test was minimal (<30 minutes' instruction and practice on two patients). The pregnant patients were easily able to dorsiflex the foot as instructed. These results demonstrate a false-positive rate of only 6%, which is consistent with the 94% specificity previously reported in nonpregnant patients.5

This preliminary study demonstrates that the gravid uterus does not appear to affect the lower-extremity venous emptying time enough to cause an unacceptable false-positive rate. Since this is an easily performed, noninvasive test, a prospective study comparing lightreflection rheography with venography and other noninvasive tests during pregnancy is currently under way.

Anticardiolipin antibody—positive serum enhances endothelial cell platelet-activating factor production

Richard K. Silver, MD, Luba Adler, MS, Andrew R. Hickman, and Joseph R. Hageman, MD

Evanston, Illinois

Circulating antiphospholipids have been linked to recurrent pregnancy loss by a mechanism involving placental and decidual thrombosis. We hypothesized that platelet-activating factor, an autacoid synthesized by vascular endothelium, might mediate this phenomenon through its ability to promote platelet aggregation and fibrin deposition. Alternatively, antiphospholipid antibodies might exert a procoagulant effect by inhibiting the synthesis of prostacyclin. To evaluate these theories, endothelial cells (harvested from human umbilical veins) were grown to confluence and incubated for 48 hours with 20% concentrations of anticardiolipin antibody-positive and -negative human sera as well as fetal bovine serum. After incubation culture wells were stimulated with 10 µmol/ml calcium ionophore A23187 (an agonist of platelet-activating factor and prostacyclin synthesis). Intracellular platelet-activating factor was measured by tritiated acetate incorporation, phospholipid extraction, thin-layer chromatography, and scintillation spectrophotometry. Enhanced platelet-activating factor synthesis was identified in cultures incubated with anticardiolipin antibody-positive serum (25,544 ± 2604 disintegrations per minute, mean ± SD) when compared with anticardiolipin antibody-negative serum (18,600 ± 3316 dpm) or fetal bovine serum (19,014 \pm 4233 dpm; analysis of variance, p = 0.033). In similar experiments, prostacyclin synthesis was determined by measuring its primary metabolite, 6-keto-prostaglandin F_{1a}, in culture supernatants. No differences between anticardiolipin antibody-positive and control cultures were observed (analysis of variance, p = 0.90). We conclude that in this endothelial cell model, anticardiolipin antibody-positive serum enhances ionophore-mediated platelet-activating factor synthesis but has no apparent effect on the production of prostacyclin. These findings suggest a potential role for platelet-activating factor in anticardiolipin antibody-mediated vascular thrombosis. (AM J OBSTET GYNECOL 1991;165:1748-52.)

Key words: Anticardiolipin antibody, platelet-activating factor, endothelial cell

Anticardiolipin antibody is among the family of circulating antiphospholipids that have been linked to adverse pregnancy outcome. It is postulated that the continuum represented by recurrent miscarriage, suboptimal fetal growth, and stillbirth is really a graded expression of a common pathophysiology, namely antibody-mediated intravascular thrombosis at the maternal-trophoblast interface. Normally the hemostatic mechanisms favoring anticoagulation predominate so that blood flow remains relatively unimpeded and thrombus formation does not occur. Antiphospholipid antibodies are thought to perturb this equilibrium, favoring thrombosis by a mechanism(s) as yet undefined.

Previous investigations have focused on the possibil-

ity that antiphospholipid antibodies decrease the concentration or potency of anticoagulant factors such as protein C, antithrombin III, or prostacyclin. ⁴⁻⁶ Observations regarding these anticoagulants have been at odds ^{6, 7} or inconclusive. ⁸ The alternative that selected procoagulant factors may be enhanced by anticardiolipin antibody has not been fully evaluated. Platelet-activating factor is known to stimulate a wide variety of biologic responses, many of which are procoagulant in effect. ^{9, 10} The ability of vascular endothelium ^{11, 12} to synthesize platelet-activating factor makes it an appealing mediator to study in the context of anticardiolipin antibody—mediated thrombosis.

Using primary cultures of human umbilical vein endothelial cells, we evaluated the hypothesis that anticardiolipin antibody—positive serum enhances the synthesis of platelet-activating factor. We also explored the possibility that production of the anticoagulant prostacyclin might be inhibited in the presence of anticardiolipin antibody. If demonstrated, these two biochemical alterations would support the presumed link between anticardiolipin antibody and altered hemostasis.

GPL units correspond to the binding activity of 1 μg/ml of purified anticardiolipin antibody. Normal values: IgG <3 GPL/ml; IgM <5 MPL/ml (SmithKline Bioscience). SAB, Spontaneous abortion; IUFD, intrauterine fetal death; SLE, systemic lupus ery-

Material and methods

Collection of serum samples. Blood was collected from seven volunteers with documented anticardiolipin antibody whose obstetric histories were consistent with antibody-mediated reproductive failure (Table I). Those with overt autoimmune disease were not receiving medication at the time of venipuncture. Samples were also obtained from seven control subjects (anticardiolipin antibody-negative without prior pregnancy loss). All sera were heat inactivated (56° C for 30 minutes), frozen (-70° C), and coded to blind the laboratory personnel. An aliquot of each sample was sent to a laboratory (SmithKline Bioscience, Van Nuys, Calif.), where enzyme-linked assays for each immunoglobulin (Ig) subclass (G, M, and A) were performed.

Endothelial cell cultures. Fresh umbilical cords (without meconium staining, identified from uncomplicated term pregnancies) were placed in sterile saline solution and refrigerated (<24 hr) until processing by the methods of Prescott et al.11 The veins were cannulated, rinsed with Hanks' balanced salt solution, and incubated with collagenase (0.1% in Hanks' balanced salt solution; Wurthington Biochemical Co., Freehold, N.J.) for 15 minutes at 37° C. The venous effluents from all cords were combined to ensure that all wells in a given experiment had an equal distribution of cells from each cord. After centrifugation (1100 rpm for 10 minutes at 25° C), the cell pellets were suspended in complete medium 199; 20% fetal bovine serum, penicillin and streptomycin (5000 units/ml each), and gentamicin (50 ng/ml), and then inoculated into 12-well culture dishes. Monolayer confluence was usually achieved in 4 to 7 days (in 100% humidity, 5% carbon dioxide at 37° C), with replacement of growth medium (minus gentamicin) at 48-hour intervals. Confirmation of cell type was accomplished by morphologic evaluation under phase contrast microscopy and by identification of factor VIII antigen. Preexperimental and postexperimental viability testing was assured by trypan blue exclusion.

Experimental design. Confluent monolayers were randomly assigned for exposure to either anticardiolipin antibody-positive or anticardiolipin antibody-negative serum, or fetal bovine serum. The serum concentrations (10% to 40%) and duration of incubation (range 1 to 48 hours) were intentionally varied during preliminary experiments. The agonist calcium ionophore (A23187) was used in all experiments because unstimulated monolayers synthesized negligible amounts of platelet-activating factor. All experiments were performed in triplicate with an individual anticardiolipin antibody-positive and anticardiolipin antibody-negative serum source. Statistical analysis was by analysis of variance and linear regression (least squares), with significance at p < 0.05.

Quantification of platelet-activating factor. Intracellular platelet-activating factor was measured according to the methods of Zimmerman et al.12 After incubation with protocol sera, monolayers were washed and then simultaneously treated with modified Hanks' balanced salt solution (containing Ca++ and Mg++), ionophore A23187, and carrier-free tritiated acetate (25μCi/ml). After a 15-minute incubation at room temperature, the reaction was stopped with the addition of 50 mmol/L acetic acid in methanol. The lipids were extracted in chloroform (15 minutes, 4° C centrifugation), dried under nitrogen, and resuspended in chloroform/methanol (9:1). Twenty-five microliters of sample solution was removed and reserved as the direct fraction; the remaining lipids were applied to silica gel plates for separation by thin-layer chromatography. Areas containing platelet-activating factor (corresponding to the synthetic platelet-activating factor standard) and the remaining lipids were scraped into separate scintillation vials for spectrophotometry. Platelet-activating factor was calculated as a fraction of the total extracted lipids and expressed as disintegrations per minute.

Quantification of 6-keto-prostaglandin Fig. Experiments parallel to those described for comparison of

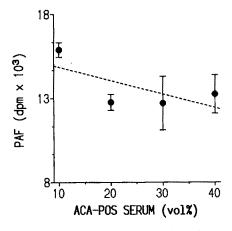

Fig. 2. Platelet-activating factor (PAF) synthesis from confluent endothelial monolayers was not affected by increasing concentrations of anticardiolipin antibody—positive (ACA-POS) serum. *Dotted line*, Linear regression $(r^2 = 0.47; p = 0.31)$.

platelet-activating factor synthesis between anticardiolipin antibody—positive, anticardiolipin antibody—negative, and fetal bovine sera were also performed to evaluate differences in prostacyclin synthesis and release. After stimulation with calcium ionophore A23187, all culture supernatants were aspirated and frozen (-70° C). A standard radioimmunoassay (Advanced Magnetics, Cambridge, Mass.) was used to quantitate this eicosanoid, which was expressed an nanograms per milliliter.

Results

Dosage of calcium ionophore. To confirm a doseresponse relationship in this model, we varied the agonist concentration and measured the corresponding

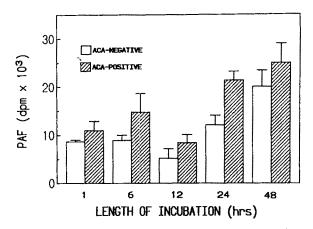

Fig. 3. Effect of varying the duration of serum exposure on platelet-activating factor (*PAF*) synthesis from confluent endothelial monolayers after incubation with anticardiolipin antibody (*ACA*)—positive and —negative serum.

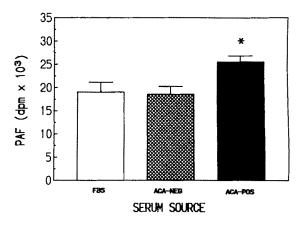

Fig. 4. Platelet-activating factor (*PAF*) synthesis from confluent endothelial monolayers after incubation for 48 hours with anticardiolipin antibody—positive (*ACA-POS*), anticardiolipin antibody—negative (*ACA-NEG*) serum and fetal bovine serum (*FBS*), all at 20% concentration. The agonist was 10 μ mol/ml A23187. Platelet-activating factor synthesis in anticardiolipin antibody—positive serum was significantly greater than in both control groups (analysis of variance, F = 5.1; p = 0.033).

platelet-activating factor synthesis. (Fig. 1; anticardiolipin antibody—positive serum from patient E, Table I). Very little platelet-activating factor was recovered in the absence of ionophore stimulation (698 \pm 79 dpm, mean \pm SD) and a dose response was observed with increasing ionophore concentration in cultures incubated with anticardiolipin antibody—positive and control sera. In subsequent experiments we chose to use $10 \,\mu$ mol/ml of the ionophore because that dose seemed to provide the most consistent response (e.g., in the range of 10^4 dpm).

Serum concentration and length of incubation. Increasing the concentration of anticardiolipin antibody—positive serum (from 10% to 40%) did not significantly

Table II. Comparison of platelet-activating factor synthesis among confluent monolayers incubated with 20% anticardiolipin antibody-positive, anticardiolipin antibody-negative, and fetal bovine serum for 48

Patient	Anticardiolipin antibody positive (dpm, mean ± SEM)	Anticardiolipin antibody negative (dpm, mean ± SEM)	Fetal bovine serum (dpm, mean ± SEM)
С	$27,302 \pm 4930$	$13,638 \pm 511$	19,904 ± 3107
D	$24,941 \pm 2337$	$20,030 \pm 1932$	$16,047 \pm 62$

Ionophore-negative culture wells used to assess unstimulated platelet-activating factor synthesis (data not shown). All other wells indicated for 15 minutes with 10 μmol/ml ionophore A23187 during tritium acetate incorporation. Data represent mean value of three experimental wells.

alter platelet-activating factor synthesis (Fig. 2; anticardiolipin antibody-positive serum from patient B, Table I). In subsequent experiments a 20% serum concentration was used.

The length of incubation appeared to influence the degree of platelet-activating factor synthesis in response to ionophore exposure (Fig. 3). The data in Fig. 3 represent two separate experiments (1, 6, and 12 hours and 24 and 48 hours) with the same anticardiolipin antibody serum source (patient A, Table I). We chose an incubation length of 48 hours for additional experiments but continued to evaluate shorter intervals if sufficient culture wells and serum were available.

Platelet-activating factor and prostacyclin production. The effect of anticardiolipin antibody-positive serum (from patients C, D, F, and G) on both plateletactivating factor and 6-keto-prostaglandin Fia synthesis was compared with the effect of control serum (anticardiolipin antibody-negative and fetal bovine serum); the raw data on intracellular platelet-activating factor recovery are shown in Table II. A significant increase in platelet-activating factor was found in monolayers incubated with all four anticardiolipin antibody-positive sera tested (Fig. 4; analysis of variance, p = 0.033). Post hoc analysis (Newman-Keuls test) revealed a significant increase between anticardiolipin antibodypositive serum and both control groups. In duplicate experiments, 6-keto-prostaglandin F1a was recovered from the culture media and quantified. No differences between anticardiolipin antibody-positive and control cultures were observed (anticardiolipin antibody-positive, 69 ± 29 ng/ml, mean \pm SD; anticardiolipin antibody-negative: 63 ± 31 , mean \pm SD; fetal bovine serum, 65 ± 23 , mean \pm SD; analysis of variance, p = 0.90).

Comment

Platelet-activating factor is an exceedingly potent lipid mediator with diverse biologic activities in health and disease. In addition to influencing aggregation and degranulation, platelet-activating factor directly influences the synthetic activity of many cell types, including neutrophils, macrophages, lymphocytes, and hepatocytes.9 Although platelet-activating factor has been proposed to participate in a variety of disease states, including diabetes, asthma, cirrhosis, and endotoxic shock, the links to connective tissue disease and to vascular thrombosis suggest a possible role for plateletactivating factor in antibody-mediated reproductive failure.

We consistently observed an enhancement of plateletactivating factor synthesis in the presence of anticardiolipin antibody-positive sera from a variety of women with adverse reproductive and medical histories. We cannot determine whether the antibody itself was the cause or if another serum factor(s) unique to these women might have promoted excess platelet-activating factor synthesis. Although we did not evaluate antibody-endothelial cell binding in our cultures, its occurrence has been demonstrated by Schorer et al.6 using similar methods. For the present, we assume that an antibody-endothelial cell interaction may contribute to anticardiolipin antibody-mediated pathophysiologic conditions, while recognizing that other cellular targets (e.g., platelets) or soluble cofactors may be involved as well.

Because a majority of newly synthesized platelet-activating factor remains stored within the endothelial cell,13 the question arises as to how its procoagulant effect is exerted within the vascular space. It has been demonstrated that platelet-activating factor is incorporated into the cell membrane,10 thus providing the opportunity to exert its chemotactic properties on platelets and other cells within the vasculature. Once platelet binding takes place, the cascade leading to thrombosis might begin. Alternatively it is possible that after prolonged endothelial cell exposure to anticardiolipin antibody the excess intracellular platelet-activating factor is only released subsequent to endothelial cell damage by a secondary mechanism. Because of its potency and its ability to promote additional eicosanoid synthesis (through arachidonic acid release from surrounding phospholipids¹⁴), a relatively small quantity of liberated platelet-activating factor may be sufficient to trigger thrombogenesis. In this regard it is also notable that the activity of platelet-activating factor's primary catabolic enzyme, acetylhydrolase, is greatly diminished during pregnancy,¹⁵ a factor that might amplify the impact of even a physiologic concentration of this autacoid. Implicating platelet-activating factor directly in the pathophysiology of the antiphospholipidantibody syndrome may ultimately have clinical ramifications because there are already specific diseases (e.g., asthma) for which clinical trials of platelet-activating factor—receptor antagonists are being evaluated.

Future studies should attempt to clarify whether the autoantibodies themselves or other factors are responsible for the enhanced platelet-activating factor synthesis observed in these experiments. Additionally, evaluation of endothelial cells from the umbilical veins of anticardiolipin antibody—positive pregnancies may confirm antibody binding and may also identify excess intracellular platelet-activating factor levels resulting from chronic in vivo antibody exposure.

Combination antibiotics and indomethacin in idiopathic preterm labor: A randomized double-blind clinical trial

Edward R. Newton, MD, Laurence Shields, MD, Louis E. Ridgway III, MD, Michael D. Berkus, MD, and Byron D. Elliott, MD

San Antonio, Texas

Subclinical infection may play a role in the failure of magnesium sulfate tocolysis. Using a double-blind randomized study design, we administered a combination of ampicillin-sulbactam and indomethacin or corresponding placebos to patients in preterm labor who were receiving intravenous magnesium sulfate tocolysis. The mean gestational age at enrollment was 30.1 weeks, and mean cervical dilatation was 2.15 cm. No differences were noted between placebo (n=43) and study patients (n=43) in gestational age at delivery, term deliveries, days gained, or neonatal outcome. Preterm delivery (<36 weeks) occurred in 61% of the total population. The likelihood of a β error was 0.07 to 0.23 on the basis of outcome analysis. In our population adjunctive ampicillin-sulbactam with indomethacin did not improve the success of magnesium sulfate tocolysis. (AM J OBSTET GYNECOL 1991;165:1753-9.)

Key words: Preterm labor, antibiotics, indomethacin

The majority of neonatal deaths, morbidity, and perinatal health care costs are associated with birth at <36 weeks. The ability of tocolytics to prevent preterm birth varies by site and study design rather than agent. In comparative trials the likelihood of tocolytic failure ranges from 28% to 81% for ritodrine, ¹⁻⁵ 39% to 61% for magnesium sulfate, ³⁻⁷ and 20% to 55% for terbutaline. ^{2-1,8} These high failure rates underline the need for better tocolytic regimens.

In the past 15 years, a wide body of epidemiologic, biochemical, and clinical evidence has supported the role of subclinical infection in preterm birth. Bacterial species differ in the strength of their association with preterm birth. However, genital tract anaerobes have been associated consistently with preterm birth by different authors and different institutions. If subclinical infection plays a role in preterm birth, then antibiotic therapy that eradicates anaerobes should prevent preterm birth in that subgroup of patients.

Tocolytic failure is associated with positive amniotic fluid cultures or an elevated C-reactive protein level. Ten to twenty percent of amniotic fluid cultures are positive in patients with idiopathic preterm labor. 14-17 With the exception of Duff and Kopelman, 16 most authors have associated positive amniotic fluid cultures with tocolytic failure. Potkul et al. 18 showed that 23 of

24 patients (96%) with normal C-reactive protein levels had successful tocolysis, whereas 10 of 16 patients (62%) with elevated C-reactive protein levels had tocolytic failure. Similarly, Handwerker et al.¹⁹ showed that 33 of 35 (94%) had tocolytic success with normal C-reactive protein levels and 11 of 15 (73%) had tocolytic failure with elevated C-reactive protein levels. Given these observations, the addition of antibiotic therapy to standard tocolytic therapy may reduce the likelihood of tocolytic failure.

The use of antibiotics has a potential to increase uterine activity transiently. The lysis of bacteria releases endotoxin from the cell walls. Subsequently, endotoxin will stimulate the macrophages to release cytokines or enzymes, which initiates prostaglandin synthesis.²⁰ As macrophage-like cells are numerous in the decidua, the surge of endotoxin-induced prostaglandins may counteract the benefits of adjunctive antibiotics. Therefore a short course of a prostaglandin inhibitor may enhance the benefits of adjunctive antibiotic therapy.

McGregor et al.²¹ in 1986 reported the first controlled trial of antibiotics in patients with active preterm labor. With subsequent support by Morales et al.²² and Winkler et al.²³ in 1988, adjunctive antibiotics seemed to reduce the incidence of preterm birth in a subgroup of patients with cervical dilatation ≥1 cm. In contrast to the latter studies, we reported in 1989²⁴ that the combination of ampicillin plus erythromycin used in conjunction with standard tocolytics failed to improve outcome.

If we assume subclinical infection to be a major cause of tocolytic failure, our discrepant results have been due to differences in study design, population differences in genital tract flora, inadequate anaerobic coverage, or an increase in uterine activity that was precipitated by a surge of endotoxin-induced prostaglandins from the lysis of bacteria. In the current study we examined the last two possibilities. Our study hypothesis was that the combination of antibiotics with anaerobic coverage (ampicillin-sulbactam) with a prostaglandin inhibitor (indomethacin) will reduce the incidence of tocolytic (magnesium sulfate) failure.

Material and methods

Subjects were selected from hospitalized patients at Medical Center Hospital in San Antonio. The Medical Center serves an indigent, predominantly Mexican-American population, who are cared for by the residents and full-time faculty at The University of Texas Health Science Center at San Antonio. The protocol was approved by the Institutional Review Board of the Health Science Center.

We used the following criteria to select eligible patients: (1) preterm gestation between 24 weeks and 33 weeks 6 days or an estimated fetal weight between 750 and 2200 gm by ultrasonographic measurement and (2) premature labor diagnosed by three contractions in 20 minutes and observed cervical effacement or dilatation or cervical dilatation of ≥2 cm and 50% effacement at initial examination.

Upper-level residents in obstetrics and gynecology, under the supervision of maternal-fetal medicine faculty, made the diagnosis of preterm labor, on the basis of cervical examination and contraction monitoring. Gestational age was determined from menstrual dating, date of pregnancy test, serial fundal height measurement, and previous obstetric ultrasonographic examination. In addition, every patient had a detailed ultrasonographic evaluation of the fetus on admission. When menstrual data were considered unreliable, a mean gestational age was determined by biparietal diameter, head circumference, femur length, and abdominal circumference. The exclusion criteria were premature rupture of membranes, suspected intrauterine growth retardation (estimated fetal weight < 10th percentile for gestational age), hypertension, known uterine anomalies, incompetent cervix, third-trimester bleeding, oligohydramnios, abnormal fetal testing, liver disease, asthma, known allergies to indomethacin or ampicillin-sulbactam, or clinical evidence of maternal infection.

The study design is depicted in Fig. 1. Tocolytic therapy was the same for both groups. We chose magnesium sulfate because it is our standard tocolytic. Preterm patients with at least three contractions in 20 minutes, with or without cervical dilatation, were hospitalized and received hydration and sedation. Only patients with contractions in spite of the latter therapy were given parenteral intravenous magnesium sulfate: a

4 gm loading dose followed by 2 gm/hr and adjusted every 30 minutes to maintain uterine quiescence (fewer than one contraction in 15 minutes) or a magnesium sulfate level of 6 to 8 mEq/dl. Of these, only patients with a cervical change or cervical dilatation \geq 2 cm and \geq 50% effacement who met selection criteria were enrolled.

Before the administration of study medications, we obtained blood for serum chemistry tests, complete and differential blood cell counts, C-reactive protein level, and an erythrocyte sedimentation rate. Vaginal Gram's stain was performed to detect bacterial vaginosis (bacterial vaginosis score ≥ 7). Vaginal cultures for aerobes and genital mycoplasmas were performed, and organisms were isolated and identified with standard techniques. A cervical sample was obtained for cultures (Neisseria gonorrhoeae) and an antigen test for Chlamydia trachomatis (Microtrak) was performed. Patients in whom group B streptococcus or C. trachomatis were identified were not treated until delivery was unavoidable.

The study medications were assigned randomly in a 1:1 ratio by the pharmacy and administered in a double-blind fashion. Patients received intravenous ampicillin (2 gm)—sulbactam (1 gm) every 6 hours for 12 doses plus concomitant oral indomethacin (50 mg loading dose, followed by 25 mg every 6 hours for seven doses) or corresponding placebos.

Indomethacin was chosen as a prostaglandin synthetase inhibitor because of its clinical experience in obstetrics in the treatment of preterm labor and the lack of neonatal effects when it is used as a tocolytic. Fetal echocardiography was performed on each fetus at 24 and 48 hours after enrollment to monitor changes in cardiac dimensions that may be related to premature closure of the ductus arteriosus. The results of the cardiac biometry were not reported to the clinicians and did not change clinical management. The findings are the subject of a separate report.

After successful therapy with parenteral tocolytics patients were treated with oral magnesium oxide (400 mg every 3 to 4 hours) or oral terbutaline sulfate (2.5 to 5 mg every 3 to 4 hours). The patients were hospitalized as long as was clinically appropriate, usually 3 to 4 days. Undelivered patients had vaginal cultures and vaginal Gram's stain repeated between 2 and 14 days after therapy.

If preterm labor necessitating intravenous magnesium sulfate recurred and in those patients whose contractions did not stop with a serum magnesium level of 6 to 8 mEq/dl, amniotic fluid was obtained by amniocentesis for Gram's stain, aerobic and anaerobic culture, and fetal lung maturity studies. If the amniotic fluid Gram's stain demonstrated bacteria or fetal lung maturity study results were positive, tocolysis was discon-

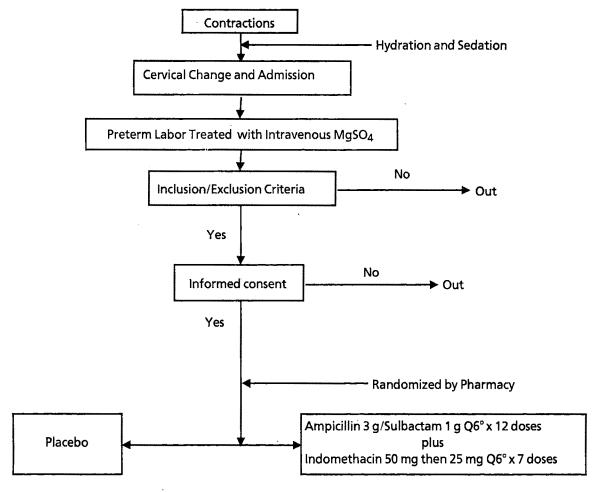

Fig. 1. Flow chart.

tinued. If the amniotic fluid study results were negative, tocolytic therapy was changed to ritodrine hydrochloride. Tocolytic failure was defined as labor with cervical dilation ≥6 cm, clinical infection, rupture of the membranes, or fetal distress and subsequent preterm birth.

Birth weight and gestational age at delivery were considered the most important outcome variables. A sample size was determined with these variables. Clinically significant increases in mean birth weight and gestational age at delivery were estimated to be 250 gm and 7 days, respectively. The variances in birth weight and gestational age at delivery were estimated to be 500 gm and 14 days, respectively. Assuming an α-error threshold of 0.05 and a power of 0.8, we determined that a sample size of 49 in each arm would be sufficient to determine significance.

Univariate analyses were performed with the Student t test and analysis of variance for continuous data. Nonparametric tests (Mann-Whitney U test) were used to confirm the validity of parametric testing and to determine the probability of differences between the groups in variables with nonnormal distributions. Cat-

egoric data were analyzed with χ^2 and Fisher's exact tests. Product limit survival analysis26 was used to describe differences in days gained in placebo and study groups. Probabilities <0.05 were considered significant.

Results

Between July 1989 and January 1991, we identified 298 laboring women who met the gestational age criteria (24 weeks to 33 weeks 6 days), who had cervical change or cervical dilatation >2 cm and cervical effacement >50% and who were being treated with parenteral magnesium sulfate. Thirty-four (14%) met the criteria but were delivered before informed consent was obtained. Most of these patients were admitted at cervical dilatations of 4 to 5 cm and were delivered shortly thereafter. Thirty-seven (15%) eligible patients either refused participation or were not identified. The remaining 88 (35%) met the exclusion criteria, including 21 (8%) with abnormal fetal test results, 15 (6%) with third-trimester bleeding, and 13 (5%) with concurrent antibiotic use. The mean birth weight of those

^{*}Change in vaginal flora at follow-up, p < 0.05.

not included in the study was 1620 ± 749 gm. Ninety-one patients (31%) met the selection criteria and were enrolled. Subsequent to enrollment, five patients were dropped from analysis, one because of delivery before study drug administration, one as a result of concurrent antibiotic therapy for a urinary tract infection at entry, and three patients who had successful tocolysis but were lost to follow-up after discharge and before 36 weeks. Forty-three placebo and 43 study drug patients were used in the analysis of outcome data. The enrollment was halted early (91 enrolled vs 98 projected patients) for administrative reasons.

Tables I and II describe the population characteristics at enrollment. Our selection criteria and randomization process created similar populations in the placebo and study drug groups except for the presence of bacterial vaginosis. The presence of more bacterial vaginosis in the placebo group than in the treatment group (38% vs 16%, p < 0.05) would bias against the placebo group and decrease an antibiotic effect. Antibiotics increased the likelihood of aerobic gram-negative rods, decreased *Lactobacillus* sp. and *G. vaginalis* at follow-up. Twelve (14%) patients underwent amniocentesis; none had an intraamniotic infection. The median times from admission to administration of study

drugs or placebo were 8 and 7 hours, respectively. This delay was not correlated with birth weight (r = 0.1, p, not significant).

Table III describes maternal outcome. There were no differences in gestational age at delivery, deliveries at >35 weeks, days gained from enrollment in the study, number of patients with recurrent preterm labor, or maternal infection (intraamniotic infection or endometritis). Fig. 2 describes the cumulative deliveries by weeks after enrollment. The curves are similar visually and statistically. Of note, 80% in both groups were undelivered at 1 week after enrollment.

Table IV depicts the neonatal outcome. Six sets of twins were enrolled (two placebo, four study drug). As a result, neonatal outcome was analyzed in 45 placebo and 47 study drug infants. There was no difference in perinatal mortality and morbidity. The net gain in fetal weight (birth weight minus estimated fetal weight) was 789 ± 674 gm in study drug patients and 645 ± 649 gm in placebo patients (p = not significant). One case of group B streptococcal disease was noted in a 2330 gm infant who was delivered 25 days after enrollment. The mother received placebo, and the culture for group B streptococcus was negative at enrollment. The infant did well. Another neonate, weighing 694 gm,

Maternal infection (No.)	6	1

was born on the third day of ampicillin-sulbactam plus indomethacin therapy. On the seventh day of life, the neonate had a clinical course consisting of sepsis and death but cultures were negative. The other perinatal death was an intrapartum death of a 750 gm, previable (25-week) fetus on the third day of ampicillin-sulbactam plus indomethacin therapy. Chorioamnionitis developed, and the fetus died during a complicated breech extraction. No autopsy was performed.

We stratified the population to identify a subgroup where antibiotics plus prostaglandin inhibitors might be of benefit. No improvement in outcome was noted in singleton gestations (n = 82), in patients at <31weeks (n = 35), elevated C-reactive protein levels (n = 52), enrollment white blood cell count >12,000 cells/mm 3 (n = 59), abnormal vaginal flora (positive group B streptococcus or bacterial vaginosis) (n = 33), or the presence of *U. urealyticum* at enrollment (n = 44). However, the likelihood of a β error as a result of small numbers is as high as 60%.

Comment

The addition of ampicillin-sulbactam plus indomethacin to magnesium sulfate tocolysis did not reduce the likelihood of preterm birth subsequent to tocolytic failure in our population. The validity of our conclusion was supported by selection criteria that identified a population where 60% were delivered at <36 weeks and <2500 gm, a randomization process that created similar populations in both treatment arms (except for the presence of bacterial vaginosis) and the probability of a β error, the likelihood of missing a true difference, of 0.23 on the basis of number of term deliveries, 0.19 on the basis of birth weight, and 0.07 on the basis of number of infants without perinatal morbidity.

The findings are consistent with our prevous study.24

Patients enrolled in the current study were at higher risk for preterm birth than were those in the former study. The differences included cervical dilatation at entry (2.15 vs 2.0 cm, p < 0.05), gestational age at enrollment (30.0 vs 31.7 weeks, p < 0.01), and estimated fetal weight at enrollment (1620 vs 1910 gm, p < 0.01). However, analysis of time gained (26 vs 34 days, p < 0.05), gestational age at delivery (34 vs 36.8 weeks; p < 0.01), and birth weight (2350 vs 2850 gm, p < 0.01) indicated more adverse outcomes in the current study.

Our results are in contrast to those of studies reported by McGregor et al.,²¹ Winkler et al.,²³ and Morales et al.²² Our studies differ in analysis when compared with the latter three studies, which reported beneficial results only in subgroups selected after randomization and during analysis. McGregor et al.²¹ randomized 58 patients and analyzed 17 patients, Winkler et al.²³ randomized 40 patients and analyzed 19, and Morales et al.²² randomized 205 patients and analyzed 150 (three treatment arms). It is possible that their subgroup selection influenced the results.

Differences in population characteristics, especially the presence of vaginal pathogens, may explain our discrepant results. The frequency of positive group B streptococcus (10%) and C. trachomatis (5%) was significantly lower in our population than in that reported by Morales et al.²² (group B streptococcus 21% and C. trachomatis 24%). However, the presence of indirect measures of decidual or parenchymal infection. i.e., elevated G-reactive protein level of elevated white blood cell count, did not improve the results of antibiotic therapy in either of our studies. Perhaps a more specific measure of subclinical decidual infection, i.e., oncofetal fibronectin, may select a population that would benefit from antibiotic therapy.

It is possible that a different antibiotic combination

or dosing schedule might improve outcome. The duration of antibiotic therapy is arbitrary. Single-dose oral therapy successfully eradicates many urogenital infections. The improvement in efficacy of ≥4 days of intravenous therapy over 3 days has not been shown. Our previous study did not show benefit with erythromycin for 7 days. In addition, ampicillin-sulbactam had a biologic affect on vaginal flora (Table II). In fact, the emergence of aerobic gram-negative rods after treatment, in spite of in vitro activity of ampicillin-sulbactam against aerobic gram-negative rods, raises the potential for clinical infection with resistant organisms.

Amniocentesis was not performed before enrollment. When it was used, i.e., for recurrent or persistent preterm labor, the amniotic fluid was not infected, a result consistent with the findings of Duff and Kopelman. ¹⁶ However, amniotic fluid infection is only an indirect measure of decidual infection, and significant decidual infection may be present with negative amniotic fluid cultures. Perhaps measures of amniotic fluid cytokines may be more predictive of decidual infection.

Although >60% of our patients were delivered at <36 weeks, magnesium sulfate tocolysis with or without ampicillin-sulbactam plus indomethacin delayed delivery a median of 26 days. A delay in delivery decreases neonatal morbidity and mortality. Delay in delivery by 1 to 2 weeks in 80% of patients has been observed consistently in controlled studies of magnesium tocolysis³⁻⁷ and was observed in the current study. However, preterm delivery after successful magnesium sulfate tocolysis remains a perplexing clinical problem.

The reasons for failure after successful magnesium sulfate tocolysis are not well described. Brustman et al.²⁷ demonstrated that patients who are delivered prematurely have more frequent contractions in spite of doseadjusted oral tocolytic therapy. Improved agents or de-

livery mechanisms may benefit this high-risk group. The role of recurrent or episodic subclinical decidual infection in this setting remains undefined.

The progesterone antagonist onapristone increases the effectiveness of oxytocin to produce delivery without changing the myometrial oxytocin receptor concentrations

Krzysztof Chwalisz, MD, PhD,^a Falk Fahrenholz, PhD,^b Mario Hackenberg,^b Robert Garfield, PhD,^c and Walter Elger, MD, PhD^a

Berlin and Frankfurt, Germany, and Hamilton, Ontario, Canada

The progesterone antagonist onapristone was used in guinea pigs during late pregnancy (43 ± 2 days after coitus) and before term (day 61 after coitus) to investigate the role of progesterone on uterine reactivity to exogenous oxytocin, concentration of oxytocin receptors, and gap junctions in the myometrium. Onapristone priming increased the ability of oxytocin to induce delivery during late pregnancy and before term by factors of ≥30 and approximately 10, respectively. The intrauterine pressure recording on day 43 after coitus revealed phasic, laborlike contractions in response to oxytocin in onapristone-treated animals, in contrast to tonic reactions in controls. The increase in the oxytocin response in onapristone-treated animals was not associated with an increase in myometrial oxytocin receptor concentrations either during late pregnancy or before term. By contrast, treatment with onapristone significantly decreased the input resistance of myometrial cells in guinea pigs in late pregnancy (43 ± 1 day after coitus) to the level of animals at term. This was associated with a marked increase in myometrial gap junctions stained with antibodies against connexin 43. These results indicate that progesterone may control myometrial reactivity to oxytocin in pregnant guinea pigs by effects on postreceptor events mainly by suppressing the gap junctions. (AM J OBSTET GYNECOL 1991;165:1760-70.)

Key words: Progesterone antagonists, oxytocin receptors, oxytocin sensitivity, gap junctions, pregnancy, guinea pig

The contractility of the uterus at the end of pregnancy depends on the release of endogenous uterotonic agents such as prostaglandins and oxytocin and an increase in responsiveness of the myometrium to these stimuli. Oxytocin is considered to play a major role in term labor. It is the most potent and specific natural uterotonic agent, and uterine contractions induced with oxytocin are identical to those occurring during spontaneous labor, providing the uterus is in a reactive state.1 The myometrium of various species, including humans, is most reactive to oxytocin either near or at the time of parturition.14 The enhanced myometrial responsiveness to oxytocin has been attributed to the increase in myometrial oxytocin receptor concentrations.2-4 Because there is no increase in oxytocin concentrations in the peripheral blood before the onset of labor in humans, it has been proposed that the increase in oxytocin receptor concentrations in myometrium

been shown in different species that in the course of pregnancy there is an increase in gap junctions, which are the structural basis of improved intercellular electrical coupling in the parturient myometrium. ⁵⁻⁷

The exact mechanism of the regulation of myometrial responsiveness during pregnancy is not clear and seems to be different in different species. In pregnant

and decidua at term is one of the primary factors lead-

ing to the initiation of parturition.⁸ However, it has also

trial responsiveness during pregnancy is not clear and seems to be different in different species. In pregnant rats the rapid increase in myometrial response to oxytocin that occurs about 1 day before term seems to be the result of a decrease in progesterone levels and an increase in estrogen levels in the peripheral blood.² By contrast, in humans^{1, 3} and guinea pigs^{8, 9} there is no decrease in serum progesterone levels before the onset of labor, and the myometrial responsiveness to oxytocin develops continuously in the course of pregnancy.

The novel 11β-aryl-substituted steroidal progesterone antagonist (antigestagen) mifepristone (RU 486)¹⁰ and the structurally related compound onapristone (ZK 98 299)¹¹ are specifically targeted to progesterone receptors and are noninvasive tools to investigate the role of progesterone in the onset of labor and myometrial response to oxytocic stimuli. A number in vitro¹² and in vivo studies in laboratory animals, ^{13,14} monkeys, ¹⁵ and humans¹⁶ have shown that antigestagens increase the myometrial responsiveness to prostaglandins and oxy-

6/6/33636

tocin. These studies indicate that the antigestagens might sensitize the uterus to uterotonic agents by increasing the receptor concentrations of oxytocin and prostaglandins and/or by postreceptor events including an elevation in gap junctions.

The current study was undertaken in late pregnancy and before term in guinea pigs to assess the oxytocin response, the oxytocin receptor numbers, and the gap junction formation after treatment with onapristone. In the preterm period of pregnancy the effect of onapristone on oxytocin response was compared with that of RU 486.

Material and methods

Animals. Female guinea pigs (Pirbright White, Charles River Wiga GmbH, Suthfeld, Germany) were kept in the presence of males and mated. The second day of vaginal opening in the fertile cycle was defined as day 1 after coitus. The animals were housed individually in an air-conditioned room (18° ± 1° C) with a light-dark regimen in which lights were on from 6 am to 6 pm. The weight of animals was between 800 and 1000 gm at 42 ± 2 days after coitus and between 1000 and 1400 gm at 60 ± 1 day after coitus. Spontaneous parturition in this strain of guinea pigs takes place overnight on day 67 or 68 ± 3 (median \pm SE).

Compounds and formulations. Onapristone (ZK 98 299) (11β-(4-dimethylaminophenyl)-17α-hydroxy-17β-(3-hydroxypropyl)-13α-methyl-4,9-gonadien-3-one) and mifepristone (RU 486) (11β-(4-dimethylaminophenyl)-17β-hydroxy-17-propinyl-4,9-estradien-3one) were dissolved in benzyl benzoate and then mixed with castor oil (1:2.25). Both antigestagens were synthesized at Schering AG (Berlin). Oxytocin (Syntocinon, Sandoz AG, Nürnberg, Germany) was diluted with 0.9% saline solution. Both the antigestagens and oxytocin were administered in 1.0 ml volume by subcutaneous injections. Control animals received the corresponding vehicle.

Induction of delivery in guinea pigs in late-pregnancy. Experiments were performed 43 ± 2 days after coitus. They were designed to establish the active threshold oxytocin dose that would induce delivery in the presence or absence (controls) of onapristone priming. The animals (n = 5 to 7 per group) were primed for 2 days (day 42 to 43 after coitus) with 10.0 mg onapristone per animal per day. Each oxytocin dose (dose range 300 to 30,000 mU per animal) was administered on the morning of day 45 after coitus either in serial injections (maximum of six injections) at 1-hour intervals (experiment 1) or, in a separate experiment (experiment 2), as a single subcutaneous injection. Controls were treated with onapristone vehicle and oxytocin. Previous studies have shown that the administration of 10.0 mg onapristone on days 42 and 43 after

coitus is effective in terminating pregnancy when given alone but the majority of animals do not deliver until the evening of day 46 after coitus^{13, 14} Animals that delivered before the first oxytocin injection were excluded from the experiment. The animals were observed continuously for 8 hours on the day of oxytocin treatment. On the following days cages were observed at least two times a day for delivered concept uses, placentas, and bleeding. The delivery of the first fetus was defined as the time of birth. Autopsy was performed on day 50 after coitus.

Induction of parturition studies. The aim of studies performed in the preterm pregnancy (61 \pm 1 day after coitus) was to evaluate the synergism of onapristone and RU 486 with oxytocin. Six to nine animals were used in each group (see Fig. 2). Onapristone (0.1 and 0.3 mg per animal) or RU 486 (0.3, 1.0, and 3.0 mg per animal) was given as a single injection on day 60 after coitus. Treatment with oxytocin was done on the morning of day 61 after coitus, 18 hours after antigestagen priming. Oxytocin was administered in serial subcutaneous injections of 25 mU per animal at 1-hour intervals until delivery or up to a total of six injections (maximum daily dose of 150 mU per animal). This dose of oxytocin was ineffective to induce preterm parturition without antigestagen priming. Previous experiments have shown that doses of >1000 mIU per animal per day (167 mU/hr) are necessary to induce birth during this period of pregnancy.9 The corresponding control groups were treated with the vehicles used for oxytocin or onapristone. The evaluation was performed as described. Autopsy was undertaken on day 70 after coitus.

Intrauterine pressure recording (day 42 after coitus). Three animals were used for each treatment and the control group. A sterile, rubber microballoon of about 0.5 ml volume filled with saline solution was inserted into the uterus on the morning of day 42 after coitus. The operation was performed with the animals under ether anesthesia. The balloon was attached to a polyethylene catheter connected to a Statham pressure transducer (Gould Inc., Oxnard, Calif.). The animals were treated on day 42 after coitus at 5 PM with onapristone 3.0 mg per animal (n = 1) and 10.0 mg per animal (n = 2) subcutaneously or with vehicle (controls). On the morning of day 43 after coitus, after an initial period of 30 minutes to record the spontaneous activity of the uterus, the animals received intravenous bolus injections of oxytocin in increasing doses of 3, 10, 30, 100, 300, 1000, and 3000 mU per animal at intervals ranging from 30 minutes to 1 hour, when the uterine activity had returned to its initial level. The intrauterine pressure was recorded over a period of 8 hours. The autopsy was performed on day 44 after coitus. The mean pressure (in millimeters of mercury) developed 1762 Chwalisz et al.

by the uterus per unit time was determined by measuring the area under the contraction curve for 10 minutes after each injection with a microcomputer-linked digitizing tablet.

Oxytocin receptor measurements. Myometrial oxytocin receptor concentrations were measured at various stages of pregnancy and post partum (for numbers, see Fig. 4) and after onapristone treatment during late pregnancy and before term. In late pregnancy the animals were treated on day 42 after coitus with subcutaneous onapristone, 10.0 mg per animal. Control animals were treated with vehicle. Each group consisted of four animals. The autopsy was performed on day 43 after coitus, 24 hours after treatment. In preterm pregnancy the guinea pigs were treated on day 59 after coitus at 5 PM either with 0.3 mg subcutaneous onapristone or with vehicle (controls). Eleven animals each were used for the treatment and vehicle control groups. The autopsy was undertaken 18 hours after treatment (day 60 after coitus).

Preparation of membrane fractions. During autopsy myometrium was separated from fat, decidual tissue, and fetal membranes. Myometrial specimens were immediately frozen in liquid nitrogen and stored at -80° C. Myometrial membrane fractions were prepared by modifications¹⁷ of the method described for rat myometrial membranes.¹⁸

Receptor binding assays. Myometrial membranes (30 to 100 µg protein) were incubated with 10 nmol/L tritium-oxytocin (specific activity 20 Ci/mmol, Amersham Buchler) at 30° C. The volume of the binding assay was 0.2 ml with the following components in the medium: 50 mmol/L Hepes and 10 mmol/L manganese chloride, pH 7.6. After 30-minute incubation, the medium was diluted with 5 ml of a cold filtration solution (0° C) containing 25 mmol/L Hepes, 2 mmol/L manganese chloride, and 0.1% bovine serum albumin. Membrane-bound tritiated hormone fraction was separated from the free hormone fraction by rapid filtration over cellulose acetate filters (0.22 µm). The filters were washed twice with the filtration medium and counted. Specific binding was obtained by the difference between tritium and ligand in the absence and presence of a 100-fold excess of unlabeled hormone. Equilibrium binding parameters were determined by a weighted nonlinear least-squares fit to logistic curves19 and by Scatchard analysis.

Electrophysiologic studies. The uterine samples from late-pregnant guinea pigs (n=8 per group) were used for the measurement of the input resistence of myometrial cells. Two groups were treated with subcutaneous onapristone 10.0 mg per animal on day 43 after coitus, and the measurements were performed 24

hours (group A) and 48 hours (group B) after the injection. The third group (group C) was treated for 2 days (day 43 to 44 after coitus) with subcutaneous onapristone 10.0 mg per animal per day. The autopsy was performed on day 45 after coitus. Two control groups were used. The first control group was treated with vehicle on day 43 and killed on day 44 after coitus. The second control group represents vehicle-treated prepartal animals on day 69 after coitus (approximately I to 2 days before the expected birth). The input resistance was measured from single smooth muscle cells with microelectrodes as used previously.¹²

Immunocytochemical staining. The animals (n = 8per group) were treated with subcutaneous onaprisotone 10.0 mg per animal per day on day 43 to 44 after coitus, and the autopsy was performed on day 45 after coitus. The control day group received vehicle. All tissues for immunocytochemical staining were rapidly frozen in liquid nitrogen and stored at -70° C until sectioning. The tissue was sectioned at a thickness of 7 to 8 µm. The polyclonal antibody that was used in this study was raised in rabbits and was directed against the cytoplasmic C terminal domain (amino acids 252 to 271) of connexin 43 (generously supplied by Elliot Hertzberg, Albert Einstein College of Medicine, New York). Sections of guinea pig heart were placed on each slide to validate the staining procedure because the guinea pig heart consistently stains with the connexin 43 antibody along the intercalated disks (see Fig. 8, C). After sections were rinsed in phosphate-buffered saline solution, 3% bovine serum albumin, and 1% Triton X-100, the primary antibody (1:250 dilution) against connexin 43 was placed on the tissue sections and they were incubated in a humidified chamber overnight at 4° C. The next day the slides were rinsed in phosphatebuffered saline solution (six times for 10 minutes each), and then a fluorescein isothiocyanate-labeled secondary antibody (goat antirabbit immunoglobulin G, Jackson Immunoresearch Laboratories, West Grove, Pa.) was added to the sections (1:200 dilution) and the preparation was incubated for 1 hour at room temperature. Afterward, the sections were again rinsed in fluorescein phosphate-buffered saline solution (six times for 10 minutes each), and then one or two drops of mounting medium (0.4% p-phenylenediamine in 0.1 mol/L sodium carbonate bufffer, pH 9, diluted 1:1 with 100% glycerol) was placed on each slide and a coverslip was applied. The sections were examined with a light microscope (Carl Zeiss, Inc., New York) ($\times 40$ to $\times 100$) with epifluorescence and filters for maximum fluorescein isothiocyanate fluorescence.

Statistical analysis. A two-sided t test ($\alpha = 0.05$) was used for statistical comparison of treatment groups

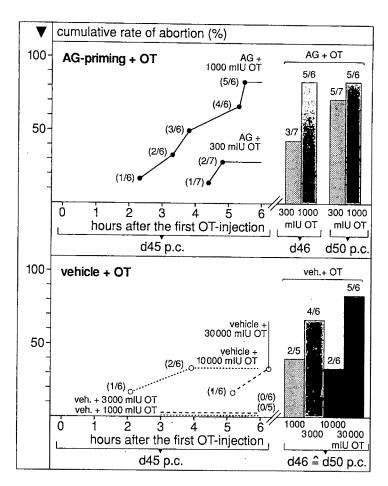

Fig. 1. Evaluation of active threshold oxytocin (OT) dose inducing abortion in presence (upper part) or absence (lower part) of onapristone (AG) priming in late-pregnant guinea pigs. with the respective control groups to obtain oxytocin receptor measurements. The Wilcoxon rank sum test was used for the analysis of the electrophysiologic studies.

Results

Induction of delivery in late-pregnant guinea pigs

Experiment 1 (serial oxytocin injections). Oxytocin showed poor effectiveness in inducing delivery in the control groups. Only a few control animals delivered on day 45 after coitus after the highest oxytocin doses (10,000 and 30,000 mU) (Fig. 1). In the treatment groups delivery was induced on day 45 after coitus in five of six animals after serial oxytocin injections at 167 mU/hr (daily dose 1000 mU per animal) and in two of seven animals at 50 mU/hr (daily dose 300 mU per animal) (Fig. 1).

Experiment 2 (single oxytocin injection). No deliveries were observed in control animals on day 45 after coitus, and intact pregnancies were found in all animals during autopsy (day 50 after coitus). By contrast, four of five and two of five onapristone-primed animals gave birth on day 45 after coitus after 3000 and 1000 mU oxytocin, respectively. A single injection of 300 mU oxytocin was not effective in inducing delivery in onapristone-primed animals.

The results of both experiments indicate that in late pregnancy onapristone treatment resulted in lowering of the active threshold oxytocin dose by the factor of ≥30. However, this value should be considered a rough approximation because nonparallel dose-response curves were compared. The experimental protocol used in these studies, which included 2 days' antigestagen priming, was used in our laboratory for routine screening of various antigestagenic compounds. Other studies have demonstrated that 1-day priming with onapristone produced a similar increase in uterine responsiveness to uterotonic stimuli.20

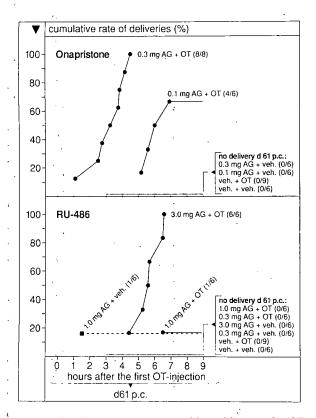

Fig. 2. Induction or preterm parturition with oxytocin (OT) after priming with antigestagens (AG) onapristone $(upper\ part)$ and RU 486 $(lower\ part)$. Oxytocin was given on day 61 after coitus in serial injections of 25.0 mU at 1-hour intervals (maximum of six injections) 18 hours after priming with onapristone, RU 486, or vehicle (controls) as described in Material and methods $(n=6\ to\ 9\ per\ group)$. Results are presented as cumulative rates of deliveries on day 61 after coitus.

Induction of parturition studies. Fig. 2 demonstrates a dose-dependent increase in oxytocin response for the induction of parturition after priming with onapristone and RU 486. Onapristone was approximately 10 times more effective than RU 486 in combination with oxytocin. After onapristone 0.3 mg per animal and RU 486 3.0 mg per animal, the normally ineffective dose of oxytocin (25 mU /hr) led to a delivery within a few hours of the start of oxytocin treatment in all animals. Significantly (p < 0.05, two-sided t test) shorter induction-delivery intervals and lower oxytocin consumption were seen in the group treated with 0.3 mg onapristone $(193 \pm 66 \text{ minutes and } 93.8 \pm 25.9 \text{ mU per animal},$ mean \pm SE) than in the group treated with 3.0 mg RU $486 (340 \pm 48.6 \text{ minutes and } 141.7 \pm 12.9 \text{ mU per}$ animal, mean \pm SE). Our previous studies have shown that at this stage of pregnancy oxytocin doses of >167 mU/hr (1000 mIU/day) were needed to achieve comparable effects in nontreated controls.9 This suggests an increase in uterine oxytocin responsiveness of approximately sevenfold to tenfold after antigestagen priming before term.

The doses of onapristone showing a synergism with oxytocin did not induce preterm birth (before day 64 after coitus) when given alone (control groups). Previous experiments have revealed that onapristone doses of ≥1.0 mg per animal are needed to induce preterm parturition without additional oxytocin treatment in guinea pigs. 18, 14 In control groups treated with RU 486 1:0 and 3.0 mg per animal approximately 50% of animals gave birth premature between the evening of day 61 or 62 and day 64 after coitus. In animals primed with onapristone or RU 486 no signs of labor were evident before the start of oxytocin treatment. However; antigestagen treatment produced bulging of fetal membranes through the cervix and vagina in some animals, which indicated that cervical softening and dilatation had occurred.

Intrauterine pressure recording. The responses to repeated oxytocin injections in the control and treated animals are presented in Fig. 3. In control animals little spontaneous uterine activity was observed before oxytocin treatment. After treatment with increasing doses of oxytocin there was an increase in uterine tone and sustained contractions of low amplitude. Even after the highest dose tested (3000 mU intravenous bolus), no regular, labor-type contractions of high amplitude were recorded. Furthermore, this dose did not induce abortion in control animals. Living fetuses were found during autopsy (day 44 after coitus) in the uteri of control animals.

In animals treated with onapristone irregular spontaneous contractions of low amplitude and relatively long duration were displayed after the injection of saline solution but before oxytocin treatment. Small doses of oxytocin (3 to 30 mU intravenous bolus) produced phasic contractions of high amplitude immediately after injection without affecting the uterine tone. The doses of 100 to 300 mU led to the rapid onset of highfrequency contractions of short duration and high amplitude that are similar to those observed during spontaneous labor. These doses led ultimately to abortion within 16 minutes to 2.5 hours in all animals treated. Analysis of the area under the contractility curves showed no basic difference between control and onapristone-treated animals. These data indicate that both groups are initially responsive to oxytocin, but the type of oxytocin-stimulated contractions differs (tonic contractions in controls vs phasic contractions in treated animals). Furthermore, the data show that oxytocin treatment leads to labor-type contractions and delivery only in the onapristone-treated animals.

Oxytocin receptor measurement

Oxytocin receptor concentrations during pregnancy and post partum (Fig. 4). The oxytocin receptor concentrations increased continuously (roughly tenfold) from day 30 to day 60 after coitus. The highest concentrations were

December 1991 Am J Obstet Gynecol

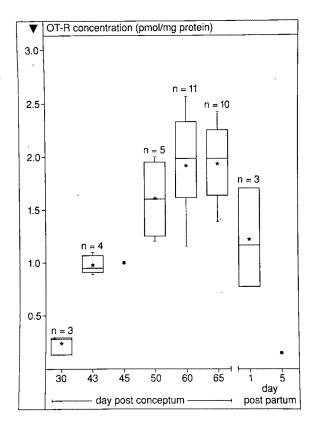

Fig. 4. Concentration of myometrial oxytocin receptors (OT-R) in guinea pig at various stages of pregnancy. Data are expressed as box plots. Vertical lines represent range from lowest to highest amount. Height of box, horizontal line, and asterisk describe interquartile range and median and mean values, respectively.

found in membranes derived from the myometrial samples of pregnant animals between day 50 and day 65 after coitus. Between day 60 and day 65 after coitus no significant change in oxytocin receptor concentration was found. Slightly lower oxytocin receptor concentrations were found on day 1 after birth.

Effect of onapristone treatment (Fig. 5). On day 60 after coitus there was no difference between the treatment and control groups (p > 0.05). However, on day 43 after coitus there was a significant (p < 0.05, two-sided t test) decrease in oxytocin receptor concentration after onapristone treatment. The equilibrium binding parameters from one onapristone-treated (0.3 mg per animal, day 59 after coitus) and one vehicle-treated animal were similar when analyzed by curve-fitting procedures and Scatchard analysis (Fig. 6). The following results were obtained in the treated and nontreated animals (values are mean \pm SE from three experiments): The apparent dissociation constants were 1.7 ± 0.1 and 2.6 ± 0.2 nmol/L, the apparent Hill coefficients were 1.2 ± 0.2 and 1.4 ± 0.2 , and the maximum binding

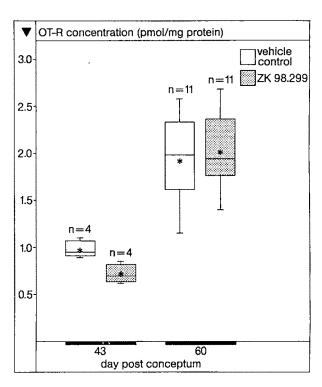

Fig. 5. Effect of treatment with onapristone (ZK 98 299) on myometrial oxytocin receptor (OT-R) concentrations in late-pregnant (day 43 after coitus) and preterm (day 60 after coitus) guinea pigs. Animals were treated as described in Material and methods. Data are presented as box plots as described for Fig. 4.

values were 2.9 ± 0.2 and 4.4 ± 0.1 pmol/mg protein, respectively.

Electrophysiologic studies. Input resistance values were significantly lower in control animals at term than in the late-pregnant controls. Onapristone treatment (groups A, B, and C) led to a significant (p < 0.05) decrease in input resistance, compared with that of the late-pregnant controls, to the level of control animals at term (Fig. 7). There was no difference between the treatment groups. When octanol (1.2 mmol/L), which is a specific gap junction uncoupling agent, was added to the recording bath, a dramatic increase in input resistance was measured in all treatment and control groups. This indicates that the decrease in input resistance that took place at term and after onapristone treatment was mainly due to the increase in gap junctions.

Immunocytochemistry. Fig. 8, A to C, shows the results of the myometrium and heart obtained with immunocytochemistry. Myometrial tissues from control guinea pigs at day 45 of gestation demonstrated little connexin 43 binding (Fig. 8, A). In contrast, myometria obtained from animals treated with onapristone for 48

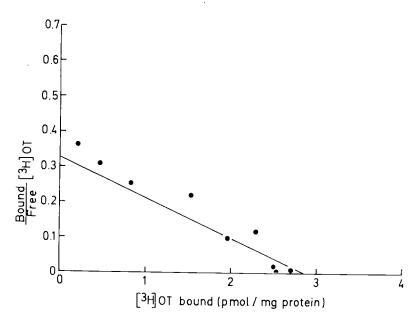

Fig. 6. Binding of ³H-oxytocin to myometrial membranes from guinea pigs treated with onapristone. Treatment and measurements were performed as described in Material and methods. Each point represents mean of three experimental values. Data are presented as Scatchard plot.

hours showed a profound increase in connexin 43 binding with punctate staining of rows of gap junctions, corresponding to the longitudinal orientation of the muscle cells (Fig. 8, B). For comparison, guinea pig heart is shown (Fig. 8, C). The connexin 43 staining between cardiac cells was limited to the region containing the intercalated discs, the position known to contain gap junctions.

Comment

The results of this study demonstrate that onapristone treatment substantially increased the ability of oxytocin to induce labor and delivery in pregnant guinea pigs. Comparable effects can be obtained before term (day 61 after coitus) with doses of this antigestagen that are approximately 30 times lower than those required in late pregnancy (43 ± 2 after coitus). This is remarkable in the light of minor differences in serum progesterone concentrations at both stages of pregnancy (approximately 1500 nmol/L 45 days after coitus vs approximately 1000 nmol/L 60 days after coitus²¹). The intrauterine pressure recording showed that treatment with onapristone converted the late pregnancy guinea pig uterus from an organ that responds tonically to oxytocin to one that reacts with phasic, laborlike contractions. Collectively, our data show that after antigestagen treatment the myometrium is more sensitive to oxytocin and is prepared for delivery.

A similar effect on uterine responsiveness to oxytocin has been shown in monkeys after RU 486 treatment. Sequential treatment with RU 486 and oxytocin was much more effective in inducing preterm parturition in monkeys than treatment with oxytocin or the antigestagen alone.15 An increase in responsiveness to oxytocin of the longitudinal and circular uterine muscle layers taken from pregnant rats treated with various antigestagenic compounds also has been demonstrated in vitro. 12 The results of our experiments are in contrast to a clinical study with RU 486 performed in the first trimester of pregnancy where the effect of antigestagen treatment on the uterine sensitivity to sulprostone (16phenoxy-tetranor-prostaglandin E2 methyl sulfonylamide) and oxytocin was investigated with intrauterine pressure recording.16 An increase in the uterine reactivity to sulprostone but not to oxytocin was found after RU 486 treatment in this study. Furthermore, no increase in the uterine responsiveness to oxytocin was found after treatment with the progesterone synthesis inhibitor epostane in early human pregnancy.22 However, the human uterus is not responsive to oxytocin during the first trimester of pregnancy, probably because oxytocin receptor concentrations are low at this time,3 whereas it is responsive to some degree to prostaglandins.1, 16 These observations would support the hypothesis that the antigestagens increase myometrial responsiveness at a postreceptor level, possibly by increasing gap junctions. Moreover, in early pregnancy antigestagens may act primarily on the endometrium and decidua rather than on the myometrium. 13, 14, 20

Previous studies have demonstrated that onapristone at doses used in this study precipitated cervical ripening

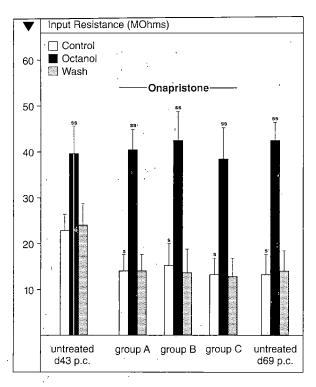

Fig. 7. Effect of onapristone treatment on input resistance of myometrial cells in late-pregnant guinea pigs. Animals were treated as described in Material and methods. White columns represent initial measurements. Black columns and dotted columns show input resistance values after in vitro treatment with octanol (1.2 mmol/L) and after tissues were washed with buffer, respectively. Values are mean \pm SE of cells that were impaled. S, Significantly different (p < 0.01) from nontreated control; ss, significant difference (p < 0.01) between control and exposure to octanol.

in both investigated periods of pregnancy. ^{13, 14, 23} Therefore the reduction of cervical resistance probably contributed in part to the effectiveness of oxytocin in inducing delivery.

The current study also demonstrates that the onapristone-induced increase in oxytocin response either during late pregnancy or before term was not due to the increase in oxytocin receptor numbers in the myometrium. On the contrary, onapristone treatment led to a significant reduction in oxytocin receptor concentration 43 days after coitus. Our data are in contrast to the results of a study performed in pregnant rabbits, which demonstrated an increase in myometrial oxytocin receptors after treatment with RU 486.²⁴ However, it is known that in this species, in contrast to guinea pigs, nonhuman primates, and humans, progesterone withdrawal leads to the onset of labor.^{1, 2} In our study oxytocin receptor measurements at different periods of pregnancy revealed a continuous, approximately

tenfold increase in receptor concentrations from early (30 days after coitus) to term (65 days after coitus) pregnancy in control guinea pigs. Similar changes in oxytocin receptors have been reported previously.4 In pregnant guinea pigs progesterone concentrations in peripheral blood show a moderate increase from early to term pregnancy and do not decrease before the onset of spontaneous labor.8, 21 The lack of an increase in oxytocin receptors after onapristone, together with the observation that rising progesterone levels throughout pregnancy accompanied the increase in oxytocin receptor concentrations, suggests that progesterone is not an inhibitor of myometrial oxytocin receptors in guinea pigs. Thus neither an acute increase in oxytocin receptors nor a change in oxytocin binding affinity is a prerequisite for the onset of labor in this species. This indicates that an increase in oxytocin sensitivity can occur preterm in this species without an increase in oxytocin receptors. The importance of changes in oxytocin receptors to the increase in oxytocin responsiveness has been questioned previously on the basis of the oxytocin sensitivity measurements in vitro of myometrial strips taken from pregnant rats at different stages of pregnancy.25 Our data provide further evidence that a rise in oxytocin receptor concentrations alone may not be the only mechanism for oxytocin to be effective. Therefore the question arises as to whether the increase in oxytocin receptor at term observed in this and other studies2-4 alone may explain the increse in myometrial sensitivity at term, which has been found in all species studied.

The electrophysiologic and immunocytochemical data convincingly demonstrate that there was a substantial increase in electrical coupling (reflected in decreased input resistance) and gap junctions in the myometrium after onapristone treatment in guinea pigs at late pregnancy. An enhanced electrical coupling as a result of the increase in density of gap junctions in the myometrium after treatment with various antigestagens has been demonstrated recently in rats.7, 12 Thus the increase in gap junction could be the major mechanism of increased responsiveness to oxytocin after antigestagen treatment. The observations that antigestagens increase the myometrial responsiveness not ony to oxytocin but also to prostaglandins and even to mechanical stimuli^{13, 14} support this conclusion. The results of intrauterine pressure measurements also are consistent with this view. Phasic and coordinated responses to oxytocin injections in onapristone-treated guinea pigs indicate that propagation of electrical events was improved by the treatment. This is the first study to describe the increase in gap junctions in the guinea pig after administration of antigestagens. Previous studies

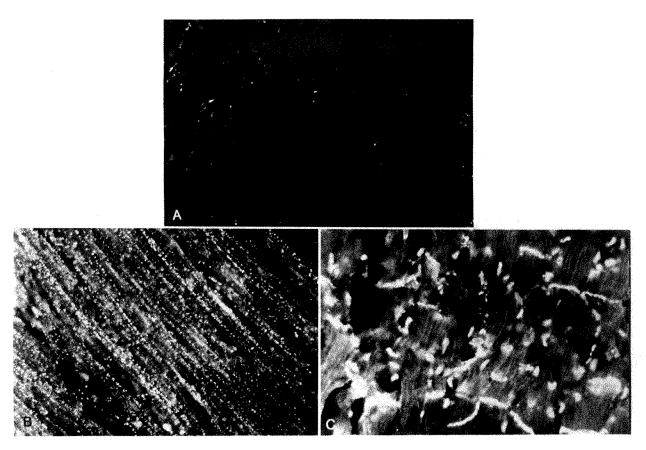

Fig. 8. Light micrograph of myometrial tissue from control animal on day 45 after coitus (A) and from animal after 2 days' treatment with 10.0 mg subcutaneous onapristone on day 43 to 44 after coitus (B) and of heart tissue from control pregnant guinea pig on day 45 after coitus (C) Treatments are explained in Material and methods. A, Note lack of staining as compared with B. B, Note abundance of bright fluorescent spots that represent gap junctions. C, Note immunostaining of intercalated discs, which confirm specificity of antibodies. (Original magnification × 1000.)

have described this phenomenon for rats after they received antigestagenic compounds.7.12 Furthermore, this is the first time connexin 43 binding has been demonstrated in the guinea pig myometrium although immunohistochemical studies of rat myometrium have been published.26, 17 However, none of the former studies quite demonstrate the dramatic differences shown in this study (Fig. 8, A vs B).

In animals primed with antigestagens no signs of labor were evident before oxytocin treatment. This observation is consistent with the concept that endogenous triggers of contractions such as prostaglandins or oxytocin are not under progesterone control in guinea pigs. 13, 14, 20 Taken together, our data provide further evidence that in guinea pigs progesterone may control uterine quiescence mainly by reducing the myometrial responsiveness, i.e., by the down-regulation of gap junctions but not by suppressing the release of endogenous uterine stimulants. This is contrary to the concept of Csapo,1 who postulated that progesterone controls both myometrial responsiveness and release of intrinsic uterotonic agents.

We are grateful to Dr. T. Louton for his expert help and advice with the statistical analysis. We thank Mrs. B. Kosub, Mrs. G. Bauer, Mr. S. Althof, and Mr. T. Goebel for their excellent technical assistance. We also acknowledge the assistance of Dr. N. Sakai with the electrophysiologic studies.

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the American Journal of Obstetrics and Gynecology

The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is \$64.50 (\$69.00 international). Prices include shipping. Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.

Contact Mosby-Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318 USA; phone (314) 453-4394. In the U.S., call toll-free: 1-800-325-4177, ext. 4394. Please allow six weeks for delivery.

Dose-related action of gonadotropin-releasing hormone on basal prostanoid production from the human term placenta

Inn Soo Kang, MD, Mi Kyoung Koong, MD, Julie Forman, BS, and Theresa Marie Siler-Khodr, PhD

San Antonio, Texas

The dose-related effect of gonadotropin-releasing hormone on placental prostanoids was studied with a perifusion system. Villous tissues were perifused with medium 199 (1 ml/hr) and at the beginning of the fifth hour, either 0, 10^{-10} , 10^{-8} , 10^{-8} , 10^{-7} , or 10^{-6} mol/L gonadotropin-releasing hormone was added to the medium of triplicate chambers. The concentration of prostaglandin E, prostaglandin F, 13,14-dihydro-15-keto-prostaglandin F_{2a}, 6-keto-prostaglandin F_{1a}, and thromboxane B₂ in the effluent medium, collected every hour, was determined by specific radioimmunoassay. The cumulative release after gonadotropin-releasing hormone treatment for each chamber was calculated, and replicate chambers were averaged. Linear regression analysis of the average for each dose from three different placentas was used to determine the dose-response relationship. Gonadotropin-releasing hormone significantly inhibited the release of placental prostaglandin E, prostaglandin F, and thromboxane B₂ in a dose-dependent fashion. Gonadotropin-releasing hormone had no significant effect on 13,14-dihydro-15-keto-prostaglandin F_{1a}, although there was an apparent increase in 13,14-dihydro-15-keto-prostaglandin F_{2a}. These data support the hypothesis that chorionic gonadotropin-releasing hormone inhibits prostanoid production from the placenta, which in turn may regulate various functions of prostanoids during pregnancy. (AM J OBSTET GYNECOL 1991;165:1771-6.)

Key words: Gonadotropin-releasing hormone, prostanoids, placenta, pregnancy, perifusion

Prostanoids in pregnancy are involved in hemodynamic regulation,^{1,2} ripening of the cervix,³ and initiation of labor.⁴ The placenta is a major source of prostanoid production during pregnancy.⁵⁻⁸ However, most studies related to prostanoid production have been carried out with amnion, chorion, or decidua, and little is known about placental production.

Previous studies of ours and others have demonstrated that synthetic gonadotropin-releasing hormone (GnRH) affects placental prostaglandins E (PGE) and F (PGF) and the 13,14-dihydro-15-keto metabolite of prostaglandin F (PGFM). Using a static explant culture system we found that either an inhibition or a stimulation of PGE, PGF, and PGFM release occurred, depending on the gestational age of the tissue and the dose of synthetic GnRH.^{5,9} Because GnRH can affect the maintenance of normal pregnancy, as demonstrated by the abortifacient actions of anti-GnRH antibody¹⁰ and GnRH antagonists or agonist in pregnant baboons, ¹¹⁻¹³ we hypothesized that GnRH may play

a role in the regulation of prostanoid production in the term placenta. In addition, we found abnormally low levels of circulating immunoreactive GnRH during pregnancy to be associated with preterm labor and delivery.14 In patients who later had postterm pregnancies, we also found higher levels of immunoreactive GnRH.15 These studies strongly suggest that GnRHlike activity during pregnancy may play a role in the maintenance of pregnancy. Therefore we believed it important to investigate the precise action of GnRH on term placental prostanoid production. This study was undertaken with a dynamic perifusion system, and the dose-response relationship of GnRH on the release of placental prostaglandins (PGE, PGF, PGFM, 6-ketoprostaglandin F_{1a} [6-keto-PGF_{1a}] and thromboxane B₂ [TxB₂]) in the human term placenta was investigated.

Material and methods

Material. Medium 199 (×2) with Earle's modified salts, sodium bicarbonate (2.5 gm/L), and L-glutamine and without phenol red (Gibco, Long Island, N.Y.), Penicillin, streptomycin, crystalline bovine serum albumin, GnRH, and indomethacin (Sigma Chemical Co., St. Louis, Mo.) were used.

Placental perifusion. Human term placentas were obtained after vaginal delivery from patients having uncomplicated pregnancies with spontaneous onset of labor. Tissues were obtained in accordance with the institutional review board protocol. Small placental tis-

sue fragments (each about 25 mm³) were dissected, excluding decidua, chorionic plate, and large fetal vessels, and then rinsed with ice-cold normal saline solution until clear in color. Tissue fragments (total weight of approximately 1 gm per chamber) were placed in 20 tissue chambers in water bath at 37° C. Each chamber was perifused with medium 199 containing 0.05% bovine serum albumin, 100 U/ml penicillin, and 100 µg/ml streptomycin, hereafter collectively referred to as medium 199. Influx medium was aerated with 95% air and 5% carbon dioxide throughout the perifusion. The oxygen tension in the medium was maintained at 100 to 150 mm Hg, that is, similar to that of the placenta in vivo. Flow rate of the media was 1 ml/hr. After a 2hour equilibration period, samples were collected hourly for 12 hours into 12 × 75 mm glass tubes containing 0.1 ml indomethacin (1100 µg/ml). The dead volume of the system was approximately 1 ml; thus it took approximately 1 hour for the influx medium to pass through the perifusion tubing and the chamber and to be collected in the sample tube. The effluent of the 20 chambers was collected simultaneously with a fraction collector (Retriever III, ISCO, Lincoln, Neb.) adapted with 20-tube rack and manifold.

Effect of GnRH on placental prostanoid release. To study the effect of GnRH on placental prostanoid release, at the beginning of the fifth hour the medium in the experimental chambers was changed to medium 199 containing 10⁻¹⁰, 10⁻⁹, 10⁻⁸, 10⁻⁷, or 10⁻⁶ mol/L GnRH. Four replicate chambers were perifused with control medium; three replicate chambers were perifused for each of the experimental media. This experimental design was repeated with placental tissues from three different patients.

Prostanoid recovery and stability. Samples were stored at -20° C until assayed for PGE, PGF, PGFM,

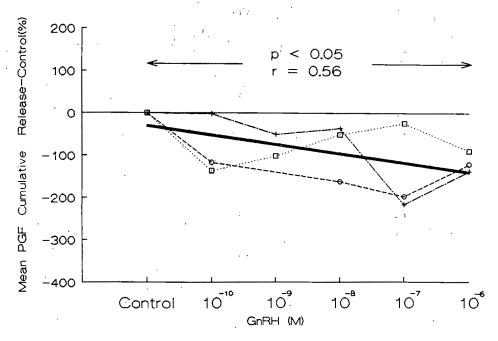

Fig. 2. Dose-related inhibitory action of GnRH on PGF production from term placenta (r = -0.56, p < 0.05). Each data point represents mean value of each placenta. Thick solid line is from linear regression analysis.

6-keto-PGF_{1α} and TxB₂. Recovery and stability of these prostanoids in this perifusion system and during storage were assessed by adding exogenous prostanoid to the influx medium and perifusing it through triplicate empty chambers and collecting samples as described above. In addition, samples were frozen and thawed repeatedly and reassayed. Prostanoid recovery and stability was 99%. Thus no data correction for procedural loss was necessary.

Radioimmunoassay. Radioimmunoassay was performed as described previously with specific exceptions as noted. After the initial pilot studies of prostanoid release of all hourly samples, samples for hours 3, 4, 5, 6, 8, 10, and 12 of perifusion were chosen for assay. All the samples from a given perifusion (placenta) were analyzed in the same assay.

PGE: A specific antiserum to PGE (Advanced Magnetics, Inc., Cambridge, Mass.) was used at a final dilution of 1/37,500. Label [5,6,8,11,12,14,15(n)-3H]-PGE₂, (Amersham Corp., Arlington Heights, Ill.), was added to every tube (25 pg). Assay sensitivity was 8 pg per tube, and the intraassay and interassay coefficients of variation were 7.8% and 9.8%, respectively.

PGF: A specific antiserum to PGF (Advanced Magnetics) was used at a final dilution of 1/60,000. Label $[5,6,8,9,11,12,14,15(n)-{}^{3}H]-PGF_{2\alpha}$ (Amersham) was added to every tube (25 pg). Assay sensitivity was 1.5 pg per tube, and the intraassay and interassay coefficients of variation were 11.0% and 10.4%, respectively.

PGFM: A specific antiserum to PGFM (Advanced Magnetics) was used at a final dilution of 1/4000. Label $[5,6,8,9,11,12,14(n)-{}^{3}H]-13,14-dihydro-15-keto-PGF_{2\alpha}$ (Amersham) was added to every tube (25 pg). Assay sensitivity was 7 pg per tube, and the intraassay and interassay coefficients of variation were 10.2% and 9.6%, respectively.

6-Keto-PGF_{1a}: A specific antiserum to 6-keto-PGF_{1a} (Advanced Magnetics) was used at a final dilution of 1/137,500. Label [5,6,8,9,11,12,14(n)- 3 H]-6-keto-PGF_{1 α} (Amersham) was added to every tube (25 pg). Assay sensitivity was 1 pg per tube and the intraassay and interassay coefficients of variation were 8.6% and 7.4%, respectively.

 TxB_2 : A specific antiserum to TxB_2 (Advanced Magnetics) was used at a final dilution of 1/70,000. Label [5,6,8,9,11,12,14(n)-3H]-TxB2 (Amersham) was added to every tube (25 pg). Assay sensitivity was 1.7 pg per tube, and the intraassay and interassay coefficients of variation were 5.3% and 5.7%, respectively.

Statistical analysis. Each prostanoid release for each chamber was first normalized to that of the fifth-hour release for that chamber. This functional normalization resulted in the least variation among replicate chambers. The integrated release from hours 6 through 12 was calculated for each chamber; mean values were obtained for each medium. The significance of doserelated effect of GnRH on prostanoid release was determined by performing linear regression analysis.

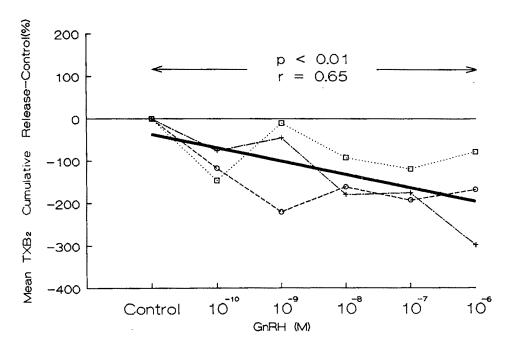

Fig. 3. Dose-related inhibitory action of GnRH on TxB_2 release from term placenta (r = -0.65, p < 0.01). Each data point represents mean value of each placenta. Thick solid line is from linear regression analysis.

Regression coefficients attaining a level of p < 0.05 were considered to be significant.

Results

The basal release of PGE, PGF, PGFM, TxB_2 , and 6-keto-PGF_{1 α} was 1165, 1212, 2625, 3249, and 237 pg/ml/gm tissue, respectively, at the fifth hour of perifusion. In control chambers the release of PGE, PGF, TxB_2 , and 6-keto-PGF_{1 α} increased over the 12 hours of perifusion (Table I). The addition of GnRH significantly inhibited PGE release from these human term placental explants in a dose-dependent fashion for concentrations up to 10^{-8} mol/L (r = -0.78, p < 0.01). However, at the higher concentration a lesser inhibition of the PGE release was noted, that is, there was a biphasic response having inhibition at the lower doses with relatively less effect at higher concentrations of GnRH ($>10^{-7}$ mol/L) returning toward control level (Fig. 1).

The release of PGF was also inhibited by GnRH, but no biphasic action of GnRH was noted in PGF release (Fig. 2). The inhibition of PGF by GnRH was dose related in the dose range studied, $(10^{-10} \text{ to } 10^{-6} \text{ mol/L}; r = -0.56, p < 0.05)$. Similarly to PGF, the release of TxB₂ from human term placental explants perifused with GnRH in medium 199 was inhibited in a dose-related fashion throughout the dose range studied (r = -0.65, p < 0.01) with increasing doses of GnRH (Fig. 3). In contrast, the release of PGFM did not decrease when placental explants were incubated with GnRH and actually increased (Fig. 4), yet this increase was not statistically significant. On the other

hand, 6-keto-PGF_{1 α} was unchanged by any dose of GnRH studied and had no noted changes throughout the perifusion period (Fig. 5).

Comment

These studies demonstrate that low doses of GnRH can inhibit placental PGE, PGF, and TxB2 production. In the case of PGE, the inhibitory effect of GnRH was observed over a shorter concentration range (10-10 to 10^{-8} mol/L) than that for PGF and TxB₂ (10^{-10} to 10^{-6} mol/L). It should be noted that the basal release of PGE, PGF, TxB₂, and 6-keto-PGF_{1a} increased over time in culture, whereas PGFM release was stable. It appears that the placental competence to produce PGFM is not stimulated by these culture conditions, yet for the other prostanoids it is increased. In addition, PGFM was the only prostanoid that increased after GnRH, although not significantly, whereas all the other prostanoids studied decreased. The stable release of PGFM and its differential response from that of PGF to enzyme inhibitors has been noted in our other studies (unpublished report, Kang et al.). These findings may indicate that GnRH acts to decrease placental PGF by inhibiting its production, enhancing its metabolism, or both.

In these studies we attempted to simulate a physiologic system by perifusing the medium with lower doses of GnRH in an air—carbon dioxide environment. The oxygen tension maintained was similar to that for the placenta in vivo. Even with a static culture system we and others have found that this environment enhances placental hormonal productions in vitro as compared with a higher oxygen tension. However, in our previous

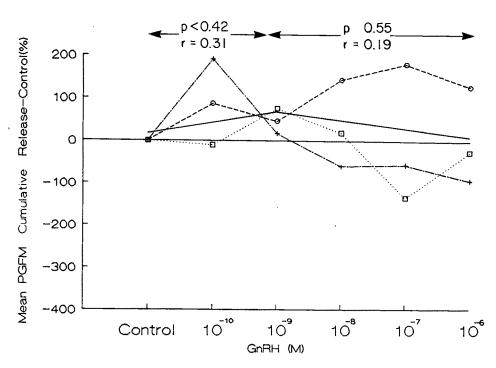

Fig. 4. Dose-related action of GnRH on PGFM release from term placenta. Each data point represents mean value of each placenta. Solid line is from linear regression analysis.

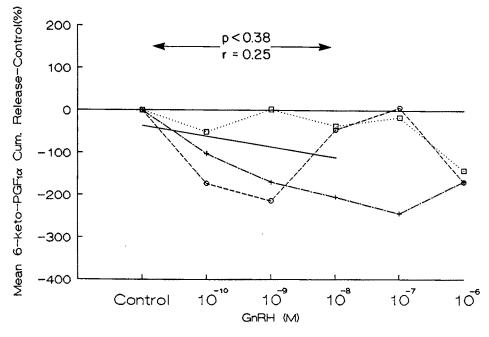

Fig. 5. Dose-related action of GnRH on 6-keto-PGF_{1α} release from term placenta. Each data point represents mean value of each placenta. Thick solid line is from linear regression analysis.

studies, which used a static culture system and GnRH at 10⁻⁶ mol/L, both inhibitory action and stimulatory action of GnRH on placental prostaglandin release were demonstrated.^{5,9} In the latter system products released from placental explants accumulated in the medium and thus the steroidal, growth factor, and other milieu was higher.

In this perifusion system the steroid and growth fac-

tor concentrations were very low because no exogenous hormones were added and the products of the tissue were continuously eluted. It is noteworthy that the prostanoid production in the perifusion system was lower than when basal steroid and growth factors were present. The magnitude of inhibition of prostanoids in these studies, although highly significant, was not marked, especially for PGF and TxB2, as has been previously observed for PGF in the first-trimester placenta with the static explant culture system. It may be that an even greater inhibitory or stimulatory action of GnRH on placental prostanoid productions may be observed in a higher estrogen or growth factor milieu. This possibility is being investigated.

These findings and our previous data demonstrate an inhibitory action of GnRH on prostanoid release in the lower, more physiologic concentrations of GnRH. On the other hand, these data appear to be in conflict with one other report in which no effect of 1.4 to 5.4×10^{-6} mol/L GnRH on PGF and a stimulatory effect of 100 nmol/L GnRH on PGF after a 4-hour incubation period were reported. However, it was difficult to compare these results because they were performed with a very different system, that is, 95% oxygen, different media, and different incubation time. It may be that in term placenta there is a biphasic response to GnRH modulated by steroids and growth factors.

In other recent studies of ours (unpublished data, Kang et al.) performed with this same perifusion system, we observed a decrease of PGF by addition of indomethacin, after which there was a decrease of PGFM. In our current study, it is interesting to note that GnRH decreased PGF release but was not accompanied by a decrease of PGFM. In contrast, an apparent increased release of PGFM was observed. Therefore this may actually reflect a greater physiologic response: PGFM was increased even when its substrate level was decreasing. Thus GnRH inhibition of PGF may reflect either or both decreased production and increased metabolism of PGF.

These data show that GnRH has a dose-related inhibitory effect on the placental PGE, PGF, and TxB2 release in vitro. This inhibitory action of GnRH may be a significant factor in the regulation of onset of labor, a theory supported by our findings that maternal circulating GnRH levels at 25 to 35 weeks' gestation were significantly higher in patients who later had post term pregnancies.15 In accordance with this finding, maternal circulating GnRH concentrations were significantly lower in four patients who later developed premature labor or delivery.14 Thus the inhibitory effect of GnRH on placental prostànoids may be a significant factor in the regulation of placental prostanoid production during pregnancy, allowing increased prostanoid release in later pregnancy when chorionic GnRH concentrations are lower.14.

Circadian myometrial and endocrine rhythms in the pregnant rhesus macaque: Effects of constant light and timed melatonin infusion

Toshihiko Matsumoto, MD,^a David L. Hess, PhD,^b Kanchan M. Kaushal, MS,^a Guillermo J. Valenzuela, MD,^a Steven M. Yellon, PhD,^a and Charles A. Ducsay, PhD^a

Loma Linda, California, and Beaverton, Oregon

Six chronically catheterized rhesus macaques maintained on a 12-hour-light/dark cycle (lights on from 7 pm to 7 pm) showed a nocturnal uterine activity rhythm with peak contractile events between 9 and 11 pm (p < 0.05). In blood samples collected at 3-hour intervals over a 24-hour period, we determined that plasma melatonin and progesterone concentrations were elevated at night whereas estradiol, estrone, and cortisol reached peak concentrations in the early morning (p < 0.05). Lights were then left on for the remainder of the study. After 12 days in constant light, daily rhythms in uterine activity and plasma steriod levels were relatively unchanged, whereas melatonin concentrations were suppressed. Animals then received a timed infusion of melatonin (0.2 mg/kg/hr each day from 7 pm to 6 pm daily until delivery). The nocturnal uterine activity rhythm and the rhythms in plasma steroid concentrations were maintained. We conclude that the 24-hour patterns in maternal uterine activity and plasma steroid hormone levels are circadian rhythms generated by an endogenous biologic clock and do not appear to be driven by the pattern of melatonin in circulation. (Am J Obstet Gynecol. 1991;165:1777-84.)

Key words: Circadian rhythm, uterine activity, melatonin, rhesus macaque

Studies in the pregnant rhesus macaque demonstrate a 24-hour rhythm in uterine contractile activity in late gestation. 1-6 Peak contractile activity normally occurs during the night between 8 PM and 2 AM. Similar rhythms are presumed to occur in women,7-9 and further confirmation has been provided by a recent study by Germain et al. (Germain A. Personal communication). The mechanisms generating these rhythms and their potential role in the process of initiation of labor remain undefined. However, preliminary data in human and other nonhuman primates9-12 suggest that births are most common at night. Since uterine activity rhythms gradually increase in intensity and evolve into labor and delivery, it is conceivable that parturition may be an extension or amplification of these normally occurring rhythms. Thus 24-hour patterns of uterine activity could serve as a predictable model for the timing of the initiation of labor.

Reprint requests: Charles A. Ducsay, PhD, Division of Perinatal Biology, School of Medicine, Loma Linda University, Loma Linda, CA 92350. 6/6/33637 Photoperiod appears to play a key role in entraining rhythms in the pregnant rhesus monkey during late gestation. We have previously demonstrated that both the uterine activity rhythm, and the timing of delivery were phase shifted by an 11-hour photoperiod shift. In addition, Figueroa et al. 13 have found that a 6-hour advance in lights off advanced the peak in myometrial contractility as indicated by changes in electromyographic activity. In addition to photoperiod entrainment of uterine activity, we have also shown that the light/dark cycle altered the 24-hour pattern of hormone concentrations in the maternal circulation such that within 1 week the various endocrine rhythms appeared to entrain to the new photoschedule. 14

In a variety of seasonal breeding species, the nocturnal melatonin rhythm mediates information about day length to time of onset and offset of reproductive function.15 During pregnancy, the melatonin rhythm conforms to the prevailing photoperiod in sheep¹⁶ and monkeys,6 with nocturnal plasma melatonin concentrations rising threefold to fivefold over daytime concentrations. At present, the specific target site for melatonin's action and the mechanism through which time cues affect normal physiologic function are unknown. We hypothesized that melatonin plays a key role in entraining the uterine endocrine system. The current study was designed to test the hypothesis that constant light with timed melatonin infusion will synchronize rhythms in uterine activity and endocrine secretion in the pregnant rhesus macaque during late gestation.

Material and methods

Animals and surgical procedures. Six rhesus macaques (Macaca mulatta) of known gestational age were obtained from the California Regional Primate Center, Davis, Calif. The animals were maintained in a controlled environment with a 12-hour-light/12-hourdark cycle during the initial portion of the study (lights on 7 AM to 7 PM; light intensity 350 lux). Animals were allowed free access to food while cleaning was performed in the morning on alternate days. Personnel were in the animal room at random times throughout the day and night for catheter maintenance, instrument calibration, and other routine tasks, as well as for the around-the-clock sampling protocols. A dim red light (<5 lux) remained on from 7 pm to 7 Am to facilitate the collection of blood samples at night. Between 115 and 120 days of gestation (term 167 days), maternal arterial, venous, and amniotic fluid catheters were surgically implanted as previously described. 4-6 After surgery, the animals were placed and maintained in a primate vest and tether system to which they were previously acclimated.¹⁷ All procedures were approved by the Institutional Animal Care and Use Committee.

Study protocol

Control photoperiod. Five to seven days after surgery, maternal arterial blood samples were collected at 3-hour intervals over a 24-hour period beginning at 9 AM, 2 hours after lights on. Additional samples were obtained ½ hour before and after lights on and lights off.

Constant light photoperiod. Immediately after the first sampling protocol, the room lights were left on for the remainder of the study. At 7 and 12 days after the start of constant light treatment, blood samples were again collected over a 24-hour period according to the sampling protocol described above.

Constant light with timed melatonin infusion. The animals remained in constant light and received a melatonin infusion (0.2 mg/kg/hr) each day from 7 pm to 6 AM until delivery. The infusion rate was modified from that of Foster et al. 18 After 7 days blood samples were again collected as described above. This sampling protocol was repeated 5 to 7 days later.

Uterine activity recording and analysis. Intraamniotic fluid pressure was monitored continuously throughout the study by connecting one of the saline solution—filled amniotic fluid catheters to an eight-channel polygraph (Gould, Cleveland) via a pressure transducer (Gould). The recorder interfaced with an IBM PC-AT microcomputer (Armonk, N.Y.) and a 12-bit analog-to-digital converter. The real-time data acquisition system and software used were described in detail elsewhere. For each uterine contraction, the amplitude, duration, time to peak amplitude, and integrated contraction area were recorded and stored on disk. Uterine activity data were analyzed as previously

described. 46 Briefly, the total contraction area for each hour of the day, defined as the hourly contraction area, was computed and used to quantify uterine activity and to evaluate the characteristics of the contractile rhythm for each animal. The mean hourly contraction area for each animal was defined as the sum of the hourly contraction areas divided by the total number of hours from the beginning of monitoring until delivery throughout the study. The hourly contraction area/mean hourly contraction area ratio was calculated for each hourly interval during a 24-hour cycle and the mean of the hourly contraction area/mean hourly contraction area ratio was used to normalize the data as previously described. 46

Assay procedures

Sample collection and storage. Maternal arterial blood samples (2 ml) were collected in chilled syringes containing ethylenediaminetetraacetic acid. Samples were centrifuged at 3500 rpm at 4° C. Plasma was separated and stored at -70° C until analyzed. Maternal erythrocytes were washed in saline solution, resuspended, and returned to the maternal circulation after each collection.

Hormone assays. Plasma concentrations of estrone, estradiol, and progesterone were assayed at the Oregon Regional Primate Research Center Radioimmunoassay Core Laboratory by previously described and validated radioimmunoassay methods. ²⁰⁻²² The intraassay and interassay coefficients of variation for the plasma estone, estradiol, and progesterone radioimmunoassays ranged from 7.8% to 12.7%.

Plasma dehydroepiandrosterone sulfate and cortisol levels were measured by direct radioimmunoassay as previously described and validated.²³ The intraassay and interassay coefficients of variation were <12%.

Adrenocorticotropic hormone was measured by direct radioimmunoassay with a commercial radioimmunoassay kit (IncStar Corp., Stillwater, Minn.). Measurement of adrenocorticotropic hormone in serial dilutions of pooled rhesus maternal plasma from late gestation gave a curve parallel to the adrenocorticotropic hormone standard curve. The intraassay and interassay coefficients of variation for rhesus maternal plasma were <10%. Assay sensitivity (defined as the smallest amount of adrenocorticotropic hormone per radioimmunoassay tube that reduces the number of counts per minute of labeled adrenocorticotropic hormone bound at zero mass by 2 SD) was 0.5 pg per tube.

Plasma melatonin was measured by radioimmunoassay with tritiated-melatonin (New England Nuclear, Boston) and a commercial antiserum (No. 704-6483, Guildhay Antisera, Guildford, Surrey, United Kingdom). Melatonin was extracted from plasma with 1 ml of glass-distilled chloroform. The chloroform phase was dried down (Hakke-Buchler vortex evaporator), rehydrated with 0.1 mol/L Tricine buffer (0.1 ml), and assayed as previously described.6 Recoveries were consistently >90% and therefore values were not corrected for procedural losses. Parallelism and quantitative recovery were confirmed in plasma pools collected from pregnant rhesus monkeys during the day and night. The limit of assay sensitivity (2 SD from buffer controls) was 0.6 pg per tube. The intraassay and interassay coefficients of variations were both <15%.

Statistical analysis. To detect 24-hour patterns, uterine activity and plasma hormone concentrations were compared with time of day by analysis of variance. Duncan's multiple range test was used for individual comparisons when the variance ratio (F) was statistically significant (p < 0.05).

Results

Uterine contractile rhythms. A rhythm in uterine contractile activity demonstrated a 24-hour periodicity (Fig. 1, upper panel); peak contractile activity occurred between 9 and 11 PM whereas the nadir occurred during the day (p < 0.05). The onset of elevated contractile activity appeared to coincide with the onset of darkness (represented by the dark bar). Daily rhythms in uterine contractile activity were not changed after exposure to constant light. Peak contractile events were observed between 9 PM and 1 AM whereas daytime activity was low (p < 0.05) (Fig. 1, middle panel). Daily melatonin infusions to the animals in constant light did not alter the uterine contractile rhythm when compared with that of previous control or constant light periods. Peak contractile activity again was observed between 9 PM and I AM with a nadir in activity in the daytime (p < 0.05). (Fig. 1, bottom panel).

The gestational age at delivery was 146.7 ± 3.5 days. After constant light with daily timed melatonin infusions, mean time of day of delivery was 7:53 PM ± 2 hours 52 minutes with a range from 3 PM to 2:30 AM.

Plasma melatonin rhythms. Plasma melatonin concentrations ranged from a nadir of 15 ± 2.4 at 7:30 PM to a peak of 57 ± 7 pg/ml at 9 PM during the control photoperiod (Fig. 2, upper panel). The nocturnal elevation in plasma melatonin level was sustained (at least from 9 PM to 12 midnight) during the dark phase whereas daytime levels were low (p < 0.01) In contrast, during constant light, melatonin concentrations throughout the period were not significantly different from daytime levels (Fig. 2, middle panel). Daily melatonin infusion (0.2 mg/kg/hr from 9 PM to 6 AM) reestablished a plasma melatonin rhythm (Fig. 2, bottom panel). Although daytime concentrations of plasma melatonin were similar to the values during the control photoperiod, the duration and amplitude of increased melatonin in circulation were greater than those ob-

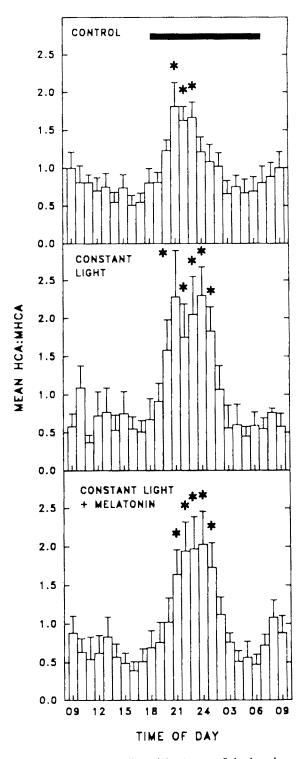

Fig. 1. Uterine contractile activity (mean of the hourly contraction area/mean hourly contraction area [HCA:MHCA] ratio) for chronically catheterized pregnant rhesus macaques. Alterations in uterine activity are represented with respect to time of day for 24 hours, during control photoperiod (upper panel), constant light (middle panel), and constant light with timed daily melatonin infusion (bottom panel). Hours refer to 24-hour clock. Periods of darkness (lights off from 7 PM to 7 AM) are indicated by solid bar in upper panel. Increases in uterine activity compared with low daytime levels are indicated by

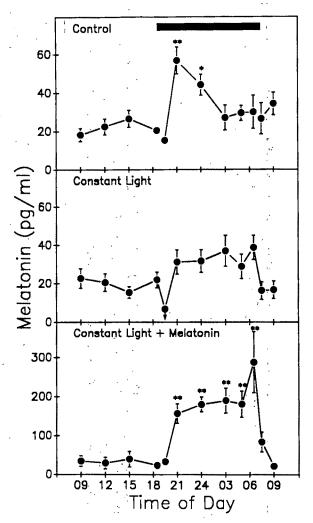

Fig. 2. Changes in maternal plasma melatonin concentrations are plotted with respect to time of day, during control photoperiod (upper panel), after 7 days of constant light (middle panel), and in constant light with timed daily melatonin infusion (bottom panel). Hours refer to 24-hour clock. Darkness during control period (lights off from 7 PM to 7 AM) is indicated by solid bar in upper panel. Values are mean \pm SE for six chronically catheterized pregnant rhesus macaques. Significant increases in concentrations compared with low daytime levels are indicated by asterisks (one asterisk, p < 0.05; two asterisks, p < 0.01). See Material and methods for details of blood sampling protocol and infusion procedure.

Plasma steroid rhythms. The 24-hour patterns of the various steroid hormones (mean ± SE) in the maternal circulation are illustrated in Figs. 3 to 7. Each figure presents data for the control photoperiod (upper panel), constant light (middle panel), and constant light with timed daily melatonin infusion (bottom panel). The solid bar in the upper panel of each figure indicates the period of darkness (lights off from 7 PM to 7 AM).

During the control photoperiod, plasma progesterone concentrations ranged from a nadir of 2.7 ± 0.3

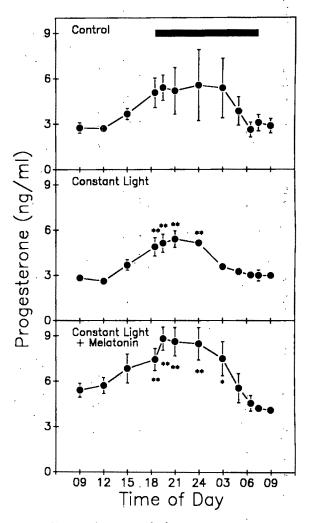

Fig. 3. Changes in maternal plasma progesterone concentrations throughout study. Refer to Fig. 2 legend for details.

ng/ml at 12 noon to a peak of 5.6 ± 2.3 ng/ml at 12 midnight (Fig. 3, upper panel). However, these differences did not reach statistical significance. In constant light (middle panel) progesterone levels ranged from a nadir of 2.6 ± 0.3 at 12 noon to a significant peak of 5.4 ± 0.5 ng/ml at 9 pm (p<0.01). Under constant light with melatonin treatment (bottom panel), the progesterone rhythm was maintained with a peak of 8.8 ± 0.8 ng/ml observed 7:30 pm (p<0.01).

Plasma estradiol concentrations during the control photoperiod range from 299 \pm 28 at 6:30 pm to 466 \pm 87 pg/ml at 5 AM (Fig. 4, upper panel). The rise in plasma during the early morning hours was not significant. In constant light, estradiol ranged from a nadir of 401 \pm 33 at 6:30 pm to a peak of 689 \pm 68 pg/ml at 7:30 AM (Fig. 4, middle panel). In addition to an elevation in mean estradiol levels, significant differences in estradiol concentrations between peak and nadir were observed (p < 0.01). With melatonin treat-

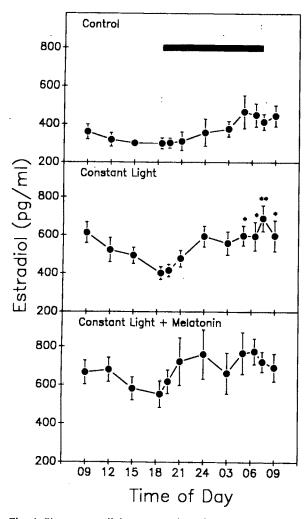

Fig. 4. Plasma estradiol concentrations throughout course of study. Fig. 2 legend contains details of study protocol.

ment, plasma estradiol ranged from 551 ± 69 at 6:30PM to 775 \pm 68 pg/ml at 6:30 AM (Fig. 4, bottom panel) but failed to demonstrate a significant rhythm as observed during the previous constant light period.

The plasma estradiol/progesterone ratio in circulation demonstrated a 24-hour rhythm throughout all phases of the study (Fig. 5). During the control photoperiod (upper panel) and constant light (middle panel) the nadir was observed at 7:30 PM, whereas the peak was noted between 6:30 and 7:30 ам. A similar pattern was observed during melatonin treatment (bottom panel). A significant difference between nadir and peak was observed throughout the study (p < 0.01).

During the control photoperiod, plasma estrone concentrations ranged from a nadir of 132 \pm 23 at 7:30 PM to a peak of 239 \pm 30 pg/ml at 9 AM (Fig. 6, upper panel). Concentrations were significantly elevated during the morning hours, 1/2 hour to 2 hours after lights on whereas the nadir occurred in the early evening (p < 0.05). During constant light this rhythm was main-

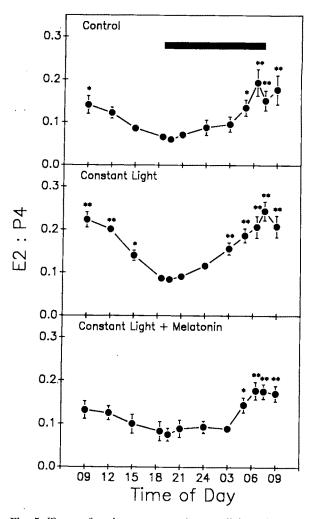

Fig. 5. Twenty-four-hour patterns in estradiol (E_2) /progesterone (P_4) ratio. See Fig. 2 legend for details.

tained and significant differences were noted between nadir (6:30 PM) and peak (6:30 to 7:30 AM) (p < 0.05). Although a similar pattern was observed with melatonin treatment the peak-to-nadir difference was not significant.

Alterations in plasma cortisol concentrations are illustrated in Fig. 7. Plasma corticol concentrations during the control photoperiod ranged from a nadir of 182 ± 12 at 6:30 pm to a peak of 319 ± 19 ng/ml at 6:30 AM. Peak concentrations in cortisol were significantly elevated in the early morning hours (p < 0.01, upper panel). Cortisol ranged from a nadir of 193 \pm 19 at 7:30 pm to a peak of $308 \pm 21 \text{ ng/ml}$ at 7:30 AM during constant light, and a circadian rhythm similar to that during the control phase was observed (middle panel). The mean values of cortisol in the early morning to noon were significantly increased as compared with the nadir value (p < 0.05). Cortisol ranged from a nadir of 192 \pm 7 at 7:30 pm to a peak of 295 \pm 23 ng/ml at 6:30 AM during constant light with melatonin supple-

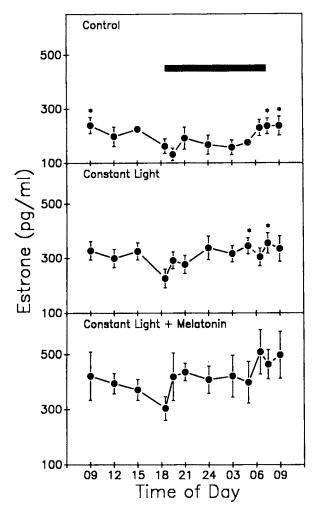

Fig. 6. Mean plasma concentrations of estrone during study. Refer to Fig. 2 legend for details.

mentation. The mean values of cortisol in the early morning were significantly elevated as compared with the nadir value (p < 0.05).

Maternal plasma adrenocorticotropic hormone concentrations ranged from 16 ± 2 to 38 ± 10 pg/ml throughout the study. Dehydroepiandrosterone sulfate levels ranged from 185 ± 35 to 240 ± 40 ng/ml. A 24-hour pattern was not observed in either of the hormones throughout the study (data not shown).

Comment

Photoperiod has a profound effect on the timing of birth in a variety of species, including humans. ⁶⁻¹² Since photoperiod also regulates the 24-hour rhythms in uterine activity in pregnant rhesus macaques, ^{6-13, 14} we tested the hypothesis that the uterine activity rhythm is endogenous, that is, it persists under constant environmental conditions. To our knowledge these studies are the first to examine the effect of continuous light on endocrine rhythms associated with pregnancy,

plasma melatonin patterns, and uterine activity. We found that the rhythms in uterine contractile activity and plasma steroid hormone concentrations remained relatively unchanged after exposure to constant light, suggesting that these rhythms are driven by a circadian mechanism involving an endogenous biologic clock. Further, the uterine activity rhythm remained unchanged even though constant light abolished the melatonin rhythm, suggesting that melatonin does not drive the uterine activity pattern. This concept is further supported by the lack of effect of a daily melatonin infusion on uterine activity and plasma hormone concentrations.

Uterine activity data from our current study are in agreement with those previously demonstrated by us⁴⁻⁶ and other investigations.^{2, 3} Contractile activity in the rhesus macaque follows a well-established pattern, with peak activity during the late night or early morning hours. The photoperiod used in these studies is similar to that of Taylor et al.² In earlier studies Harbert and Spisso¹ used 12-hour-light/12-hour-dark cycles as well. However, in their study the lights were on from 4 AM to 4 PM and peak contractile activity occurred approximately during daylight hours. Differences in the time of peak contractile activity among these studies appear to be the result of an entraining effect of the light/dark cycle.^{4, 6, 13}

There is abundant evidence in human and nonhuman primates that light/dark cycles are the principal zeitgebers, capable of entraining physiologic circadian rhythms.24 In seasonal breeding species, including the rhesus macaques, photoperiod control of the circadian pineal melatonin rhythm is suggested to regulate reproductive function and endocrine secretion.25 In our previous studies in the pregnant rhesus macaque, 6, 14 when the light cycle was shifted, a parallel shift in melatonin rhythms was observed along with alterations in other maternal hormones and uterine activity. These findings raise the possibility that in the rhesus, as well as other seasonal breeders,15 the 24-hour melatonin rhythm conveys information about the photoperiod and synchronizes various maternal endocrine rhythms to the light/dark cycle. In the current study plasma melatonin levels in the maternal circulation demonstrated a 24-hour rhythm during the control photoperiod with peak concentrations attained at 9 PM whereas daytime concentrations were low. However, the absence of a melatonin rhythm under constant light conditions (mean values over 24 hours were similar to daytime levels) was associated with the persistence of a rhythm in uterine contractile activity. During the melatonin infusion, mean levels exceeded those observed during the peak of the nighttime rise during the control photoperiod by approximately fourfold. Studies by Ebling et al.26 in the sheep and Goldman et al.27 in the hamster have shown that the amplitude of the nocturnal rise in melatonin is not what determines the photoperiodic response. The duration of the rise must be sufficient to elicit a response. The duration of the melatonin rise induced by the infusion was sufficient when compared with that of the controls. These data fail to support our original hypothesis and indicate that melatonin may not play a key role in entraining the uterine endocrine system under constant light conditions. Moreover, the findings raise the question of whether melatonin plays a role in the photoperiod-mediated process that times the onset of labor.

A number of hypotheses have been proposed to explain the factors responsible for the generation of 24hour patterns in plasma steroid concentrations in the pregnant rhesus macaque. Sholl et al.28 suggested that the nocturnal increase in maternal progesterone levels reflects an alteration in placental secretion, as a result of either changes in blood flow or altered placental steroidogenesis. The blood flow hypothesis seems unlikely because uterine contractions occurring maximally at night2-6 decrease placental blood flow and would limit the availability of substrate for placental steroidogenesis at a time when progesterone levels are rising. A more plausible hypothesis was proposed by Hess et al.29 They postulated that the diurnal cortisol secretion by the maternal adrenal changes the displacement of progesterone from common binding sites on plasma proteins. Therefore the inverse patterns in plasma progesterone and cortisol are the result of altered binding of progesterone to plasma proteins because adrenal activity (cortisol secretion) varied throughout the day. However, the factors responsible for the daily alterations in adrenal activity remain undefined.

The circadian uterine activity rhythm may depend on rhythms in plasma steroid levels. Estrogen concentrations have been demonstrated to have profound effects on uterine contractility. Elevated estradiol/progesterone ratios have been associated with increased contractile activity in the rabbit30 and sheep.31 On the basis of these studies, data in the rhesus monkey appear on the surface to contradict findings in other species. As shown in Fig. 5, the peak estradiol/progesterone ratio was observed in the early morning followed by a nadir in the evening. The nighttime peak in the uterine activity rhythm (between 8 PM and 1 AM) occurs when estradiol/progesterone levels are around nadir and progesterone levels are elevated, that is, the estradiol/progesterone ratio is at its lowest (Fig. 5). However, Roberts et al.32 demonstrated that estrogen increases myometrial adrenergic receptors in as little as 6 hours and with maximum responsiveness at 12 hours. Thus peak levels in estrogen may require up to 12 hours to maximally influence myometrial responsiveness to circulating uterotonins. This is precisely the time

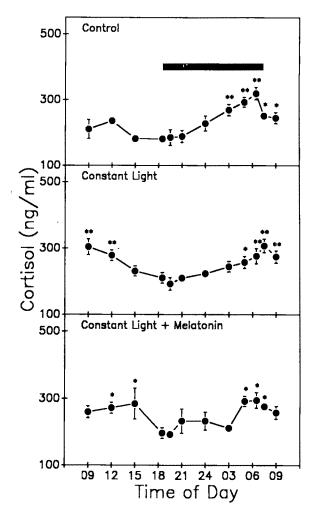

Fig. 7. Changes in plasma cortisol concentrations throughout study. See legend to Fig. 2 for details.

lag between the peak in estrogen concentrations in maternal plasma and the first significant increases in uterine contractile activity. Thus the circadian rhythm in estrogen levels or the estrogen/progesterone ratio may still play a crucial role in the regulation of myometrial contractile rhythms.

Data from the current study confirm that 24-hour rhythms in circulating plasma steroid levels are a characteristic of pregnancy in the rhesus macaque during late gestation^{6, 14, 33, 34} and extend these observations to include maintenance of these rhythms under constant conditions. Taken together with our previous observation that these rhythms reentrain to an altered photoperiod, these results suggest that photoperiod may entrain the rhythms, but the rhythms are ultimately the result of an endogenous pacemaker.

In conclusion, photoperiod has been shown to profoundly affect endocrine rhythms^{6, 14} and uterine contractile rhythms.6, 13 In this study uterine activity and plasma steroid hormone rhythms were found to persist under constant conditions. These data further strengthen the concept that these 24-hour patterns are circadian rhythms generated by an endogenous biologic clock.

Effects of intravenous cocaine on reproductive function in the mated rabbit

Susan J. Atlas, PhD, and Edward E. Wallach, MD

Baltimore, Maryland

A dramatic increase in the use of crack cocaine by young women has resulted in the exposure of a substantial number of fetuses to the drug in utero. The goal of these experiments was to investigate the effects of intravenous cocaine (a model for crack) on reproductive function in the female rabbit. We used two protocols: (1) single daily injections over the course of pregnancy ("single daily" protocol), with animals examined on day 1, 8, 15, 22, or 29, and (2) six hourly injections on the day of mating ("binge" protocol). The maximum tolerated dose of cocaine, 4 mg/kg, was administered at 0.5 ml/min. The single daily protocol increased ovulation but had no effect on fetal and placental weights or preterm delivery. The binge protocol significantly reduced in vitro development of retrieved embryos but did not affect implantation assessed on day 8 of pregnancy. (AM J OBSTET GYNECOL 1991;165:1785-90.)

Key words: Cocaine, rabbit, ovulation, implantation, pregnancy

Crack, the smoked form of cocaine, is used by a substantial percent of pregnant women,1 and use of the drug is associated with decreased birth weight and increased preterm delivery.2.3 The pharmacokinetics of cocaine is dependent on the route of administration. Both smoking crack and intravenously injecting cocaine produce extremely high circulating levels of the drug almost instantaneously, and nasal insufflation ("snorting") and subcutaneous administration yield lower circulating levels that reach a peak 30 minutes to 1 hour after administration.4 Most animal studies of the effects of cocaine on female reproduction have used the subcutaneous route,5,6 which is a good model for nasal insufflation but may not produce the effects of the high levels and rapid increase in plasma cocaine that are seen with crack use.

The overall goal of these experiments was to investigate the effects of intravenous cocaine (a model for crack) on reproductive function in the female rabbit. We have modeled two patterns of crack use, daily usage and less frequent binging, with two experimental protocols: (1) single daily injections over the course of pregnancy (single daily) and (2) six hourly injections on the day of mating (binge). Control rabbits were in-

jected with equal volumes of the saline solution vehicle. The specific purposes of the single daily protocol were to examine ovulation, fetal, placental, and corpora lutea weights, and progesterone levels in animals treated with either cocaine or saline solution. We also examined the effects of the higher-dose binge protocol on early reproductive events, such as ovulation, early embryonic development, and implantation.

Material and methods

Animals. Adult New Zealand White does weighing 3.5 to 6 kg were obtained from Bunnyville Farms (Littlestown, Pa.) and were housed individually in our animal quarters for 3 weeks before use under controlled light (14 hours light-10 hours dark; lights on at 7 AM) and temperature (21.1° to 22.2° C). Animals had free access to rabbit chow and water. Studies were performed in accordance with the Guidelines for the Use of Experimental Animals at the Johns Hopkins University. Each female rabbit was brought to a male's cage, and the pair was observed for successful mating. If no attempt at mating occurred within 1 minute, the female was placed in the cage of another male. Mating was confirmed by observation of sperm in a vaginal smear. The day of mating was designated day 0 of pregnancy (term is normally day:31 or 32). Four males of established fertility were used in the experiments. The female rabbit was weighed immediately after mating, and cocaine (Sigma Chemical Co., St. Louis) or saline solution vehicle was injected into the marginal ear vein. Cocaine solutions were made fresh weekly in sterile saline solution and were stored in the dark. The delivered dose of cocaine was 4.0 mg/kg, which was administered by infusion pump in a volume of 0.25 ml/kg at a rate of 0.5 ml/min. Approximately 10% of the rabbits expe-

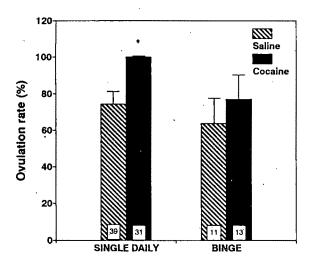

Fig. 1. Ovulation rates in mated rabbits subjected to single daily and binge protocols. Ovulation rate = (Number of animals ovulating/Number of animals mated) \times 100. All animals that received cocaine in single daily protocol ovulated (asterisk, p < 0.01, compared with saline solution controls). There were no differences between saline solution and cocaine groups with binge protocol. Number of animals mated is indicated within bar.

rienced drug-induced convulsions that resulted in traumatic vertebral fracture and lower limb paralysis. Those animals were killed with pentobarbital sodium.

Single daily protocol. Rabbits were weighed, and the cocaine (n = 31 rabbits) or saline solution (n = 39) was injected daily between 8 and 11 AM. On day 1, 8, 15, 22, or 29 of pregnancy, 24 hours after the last cocaine or saline injection, rabbits (n = 5 to 8 per treatment for each day examined) were anesthetized with pentobarbital sodium (32 mg/kg), and a laparotomy was performed. Heparinized blood samples were obtained from each cannulated ovarian vein8 and from the periphery (vena cava) for progesterone determination. Plasma samples were stored at -70° C until they were assayed. The numbers of corpora lutea and unruptured follicles ≥1.5 mm in diameter were recorded on day 1. On subsequent days ovaries and pregnant uteri were removed; corpora lutea were dissected from each ovary, pooled, and weighed; and the number of implantations per side was ascertained. On days 15, 22, and 29 fetuses and placentas were separated and those contained in each uterine horn were pooled and weighed. Ten other females were mated and weighed daily but were not restrained or injected. These untreated controls were killed on day 29, and the corpora lutea, fetuses, and placentas were counted and weighed as previously described.

Binge protocol. Animals were mated and weighed, and a blood sample was drawn from the marginal vein of one ear (cocaine n = 9; saline solution n = 6 rabbits). The first dose of cocaine or saline solution was

administered as previously described through the marginal ear vein of the contralateral ear. Blood sampling and cocaine or saline injection were repeated once an hour for a total of six injections. Plasma was stored at -70° C until it was assayed.

Twenty-four hours after mating (day 1), a peripheral blood sample was drawn, animals were anesthetized with pentobarbital sodium, and a laparotomy was performed. A blood sample was collected from each ovarian vein, and the ovary, fallopian tube, and proximal portion of the uterine horn were removed en bloc from each side and placed in saline solution. Ovaries were inspected for the number of corpora lutea and unruptured large follicles (diameter ≥ 1.5 mm). Ova and embryos were recovered by flushing fallopian tubes with Ham's F-10 medium (Gibco, Grand Island, N.Y.). Embryos recovered from a single tube were cultured together in vitro in Falcon organ culture dishes (Becton Dickinson, Lincoln Park, N.J.) containing 0.7 ml Ham's F-10 medium plus 20% fetal calf serum (Gibco), 0.1 mg/ml gentamicin (Gibco), and 31 µg/ml penicillin-G (Sigma). Embryonic development was assessed daily for six days in accordance with a treatment-blind protocol.

To assess the effects of the binge treatment on implantation, the binge protocol was repeated with another group of rabbits (cocaine n=4; saline solution n=4). These animals were not disturbed after mating and repeated dose administration. On day 8 of pregnancy a peripheral blood sample was taken from the lateral ear vein, and the implantations per uterine horn were counted. Corpora lutea were also counted, dissected from each ovary, pooled, and weighed.

Progesterone determinations. Progesterone in peripheral and ovarian vein plasma samples were determined in duplicate by a solid-phase radioimmunoassay (Diagnostic Products, Los Angeles).8

Data analysis. The unit of analysis for most measurements was the side: Rabbits have two cervices, and the left and right reproductive units (ovary, fallopian tube, and uterine horn) are totally separate. Corpora lutea and fetal and placental weights and numbers, as well as ovarian vein progesterone determinations, were treated as repeated measures for left and right sides within each rabbit. These data were analyzed by twofactor analysis of variance with one repeated measure (left and right sides). Ovulation rate (the percent of mated rabbits that ovulated), ovulatory efficiency (the percent of follicles ≥ 1.5 mm in diameter that ovulated by 24 hours after mating), preimplantation development, and implantation index (the number of implantations per number of corpora lutea) were analyzed by use of 2 × C contingency tables. Yates' correction was used for 2 × 2 tables. Rabbit weight gain was assessed by multivariate regression; the day of pregnancy, initial weight, and treatment group (cocaine, saline solution,

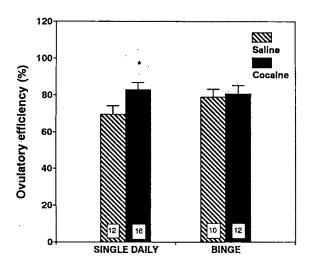

Fig. 2. Ovulatory efficiency among animals ovulating, as assessed on day 1 of pregnancy. Ovulatory efficiency = (Number of corpora lutea/[Number of corpora lutea + follicles ≥ 1.5 mm]) × 100. Ovulatory efficiency in animals receiving single injection of cocaine was significantly higher (asterisk, p < 0.05) than that of saline solution controls. There was no difference in ovulatory efficiency with the binge protocol between animals treated with cocaine and those that received saline solution. Number of ovaries examined is indicated within bars.

or untreated control) were used as the independent variables. Differences with p < 0.05 were considered significant.

Results

Single daily protocol

Ovulation. All the animals receiving daily cocaine injections ovulated, as compared with only 74% of the saline solution controls (p < 0.01, Fig. 1). Moreover, ovulatory efficiency in animals that ovulated was significantly higher in animals receiving cocaine than in saline solution controls (cocaine, 101 ovulations from 122 large follicles; saline solution, 68/98; p < 0.05, Fig. 2). Cocaine administered in the single daily protocol did not stimulate ovulation in unmated animals (data not shown).

Weight gain. Data from groups of rabbits subjected to laparotomy on day 22 and day 29 of pregnancy were combined, and the analysis is based on data through day 22. No change in the pattern of weight gain was seen between day 22 and day 29. Weight gain was reduced in the cocaine-treated animals when compared with the saline solution-treated controls (p < 0.0001, Fig. 3). However, the untreated animals gained weight at a significantly higher rate than did either of the treated groups (p < 0.0001).

Fetal and placental weights. In spite of the difference in maternal weight gain, average fetal and placental weights on days 15 and 22 of pregnancy were similar

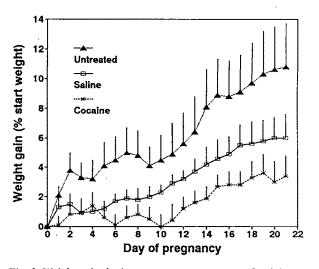

Fig. 3. Weight gain during pregnancy as percent of weight on day of mating. Animals were weighed daily: untreated (n = 5), single daily injection with saline (n = 8), single daily injection with cocaine (n = 9). Restraint and injection decreased weight gain as compared with that of untreated animals (p < 0.0001), and cocaine-treated animals gained less weight than did saline solution-treated controls (p < 0.0001).

in animals injected daily with saline solution or cocaine (Table I). On day 29 fetal and placental weights were similar in both untreated animals (fetal 37.8 ± 1.5 , placental 4.28 ± 0.19) and animals injected with cocaine or saline (Table I). The average number of fetuses per uterine horn was not affected by cocaine treatment (data not shown). Delivery in this strain of rabbits is expected on day 31 or 32 of pregnancy9; however, none of the rabbits subjected to the single daily protocol delivered by day 29.

Corpora lutea weight and progesterone levels. No significant differences in the average weight (Table II) or number of corpora lutea per ovary (data not shown) were found between cocaine- and saline solutiontreated groups. Average corpora lutea weight in the day 29 untreated control group was 21.2 ± 0.73 , which was similar to weights for both the treated groups.

Peripheral and ovarian venous progesterone levels in treated animals were examined on days 1, 8, 15, 22, and 29 of pregnancy (Table II). Peripheral progesterone levels reached a peak at midgestation and then declined. In contrast, ovarian vein progesterone levels rose dramatically from day 1 to day 8 and remained high through day 29. There were no significant differences between the cocaine- and saline-treated groups with respect to peripheral or ovarian vein progesterone levels.

Binge protocol. There were no differences in occurrence of ovulation (Fig. 1) or in ovulatory efficiency between cocaine (62/77 follicles) and saline solution (63/80 follicles) groups (Fig. 2). Fifty embryos were

recovered from 6 rabbits treated with cocaine in the binge protocol, and 40 were recovered from 5 saline solution—treated control animals. Although similar numbers of embryos per rabbit were recovered from the two groups, developmental stages were significantly different by the sixth day of in vitro culture (2 × 4 contingency table, $\chi^2 = 14.62$, p < 0.005). More of the embryos from cocaine-treated rabbits were arrested in the one-cell to four-cell stage (p < 0.05) or remained in the morula stage (not significant, p > 0.1), and significantly fewer had reached the blastocyst stage (p < 0.01; Fig. 4) than had those from saline solution—treated rabbits. However, no difference in implantation index between cocaine- and saline solution—treated an-

imals was found on day 8 of pregnancy (Fig. 5). Because implantation in the saline solution group in preliminary experiments was uniformly high and was no different from that observed with any other group (Fig. 5), it was decided that increasing the number of animals in this group was not necessary.

Comment

Most of the animals tolerated both protocols well. However, 4 mg/kg administered at 0.5 ml/min was found to be the highest dose schedule tolerated by this group of female rabbits; increasing the dose to 4.5 mg/kg or the rate of administration to 1.0 ml/min often resulted in severe convulsions. The binge protocol, al-

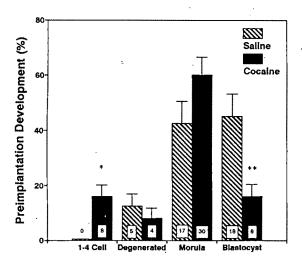

Fig. 4. Embryonic development in vitro assessed on sixth day of culture. Animals were mated and treated with binge protocol. The next day ova and embryos were retrieved and cultured in vitro for 6 days. Fifty embryos were recovered from 6 cocaine-treated rabbits, and 40 were recovered from 5 saline solution-treated control animals. An increased percent of embryos from animals treated with cocaine remained at one-cell to four-cell stage (asterisk, p < 0.05) or morula stage (not significant), and a decreased percent reached blastocyst stage (two asterisks, p < 0.01) as compared with embryos of saline solution-treated controls. Numbers of ova and embroys at each stage are indicated within bars.

though high dose, is within the range seen in compulsive cocaine users who report repeated crack or intravenous cocaine administration at 20- to 40-minute intervals for as long as 24 hours.7

In rabbits, failure to ovulate after mating is probably the result of inadequate luteinizing hormone surge.9 Acute injections of cocaine have been shown to stimulate luteinizing hormone release in rats and monkeys,10,11 whereas repeated cocaine injections before the ovulatory stimulus decrease ovulation in the cycling rat⁵ and mated rabbit⁶ and are associated with decreased serum luteinizing hormone levels.5 These data suggest that the increased ovulation rate observed in rabbits treated with cocaine by the single daily protocol may have been a result of the acute effect of the drug on the hypothalamopituitary unit. The ovulation rates observed in animals treated with saline solution by the single daily protocol or with cocaine or saline solution by the binge protocol and in untreated controls were essentially identical and similar to published ovulation rates for mated rabbits.9

In many species, including humans, cocaine use causes anorexia12 and an attendant reduction in weight or weight gain.13, 14 Some experimenters have found that cocaine treatment during pregnancy reduces fetal or newborn rodent weight,15,16 although others have found that weight is not affected.17, 18 The single daily protocol reduced maternal weight gain in rabbits, but

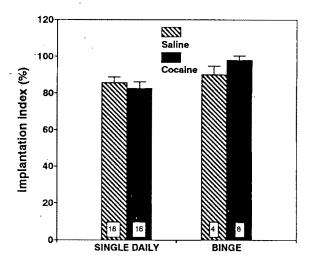

Fig. 5. Implantation index on day 8 of pregnancy in animals subjected to single daily and binge protocols. Implantation index = (Number of implantations/Number of corpora lutea) × 100. There was no difference in implantation index between cocaine and saline solution treatment with either protocol. Number of sides (ovary and ipsilateral uterine horn) examined are indicated within bars.

decreased maternal weight gain did not affect fetal or placental weights. This is not surprising, because restricting maternal food intake to <50% of the minimum requirement only slightly decreases rabbit fetal weight.19 In some drug studies it may be necessary to include a control group that is pair-fed to the same food and water intake, or perhaps weight gain, as the cocaine group. Because the significant differences between cocaine and saline solution groups (ovulation rate, ovulatory efficiency, and effects on subsequent in vitro development when embryos were retrieved on day 1) were seen within 24 hours of starting treatment and before nutritional status would have been affected, there was no need for a pair-fed group in these experiments.

Kaufmann and Savoy-Moore²⁰ found that rabbits injected with cocaine subcutaneously for 5 days before gonadotropin-induced ovulation had lower serum progesterone levels than did saline solution-treated controls. This observation suggests that repeated exposure to cocaine may affect subsequent luteinization. However, we did not observe similar effects in our studies in which the cocaine regimen was begun immediately after mating. Peripheral venous progesterone levels in both cocaine and saline solution groups over the course of pregnancy were similar to those reported by Mikhail et al.21 for untreated rabbits. Average corpora lutea weight during the course of pregnancy was also similar to previously reported values.22 In contrast, ovarian venous progesterone levels in both cocaine- and saline solution-treated groups rose earlier in the pregnancy and remained high longer than did those previously reported for pregnant rabbits.²² It is possible that the daily routine of restraint and injection with cocaine or saline solution increased progesterone secretion into the ovarian vein. Increases in progesterone clearance may have compensated for increased secretion, so that peripheral levels were similar to those seen in normal pregnant rabbits.

The binge protocol exposed follicular oocytes to repeated doses of cocaine between the gonadotropin surge and ovulation, during nuclear and cytoplasmic maturation.²³ Cocaine induces temporary delays in maturation in several systems of the neonatal rat.¹⁶ The decrease in blastocyst development in vitro that we observed with the binge cocaine protocol may have been a similar temporary developmental delay, which may have resulted from cocaine-induced alterations in cytoplasmic maturation. By the time of implantation the previously delayed embryos may have progressed sufficiently so that the implantation of embryos from both cocaine- and saline solution—treated rabbits was similar.

Human cocaine use has been correlated with a decrease in birth weight and an increase in preterm delivery.^{2,3} Is this poor outcome a result of effects of the drug, of the life-style that accompanies use of the drug, or of the interaction between the factors? Although there are dangers in extrapolating observations across species, our results suggest that exposure to the drug alone is not sufficient to account for the poor pregnancy outcome seen in crack users. We found that daily exposure to high levels of cocaine does not reduce fetal weight or result in preterm delivery. It seems likely therefore that the interaction of the drug with accompanying risk factors, such as poor nutrition and a lack of prenatal care, is responsible for the perinatal problems associated with human cocaine use.

We thank Marian W. Fischman, PhD, and A. M. Dharmarajan, PhD, for their valuable critique, as well as Terry Feng, MD, for his assistance with the experiments. We also acknowledge the technical assistance of Ms. Beverly Smith, Ms. Lillian Dasko, and Ms. Fran Karas in preparation of the manuscript.

Expression of extracellular matrix—degrading metalloproteinases by cultured human cytotrophoblast cells: Effects of cell adhesion and immunopurification

Paul Bischof, PhD, Evelyne Friedli, MSc, Marzia Martelli, MSc, and Aldo Campana, MD Geneva, Switzerland

In vitro, invasion of basement membrane by human trophoblast can be blocked by metalloproteinase inhibitors. The purpose of our study was to characterize these enzymes by zymography, to define their cellular origin. First-trimester cytotrophoblast cells were prepared according to the method of Kliman et al. Half of the cell suspension was further purified with an antibody to leukocyte common antigen (CD45). Cytotrophoblast cells (immunopurified or not) were incubated in Dulbecco's modified Eagle's medium on different matrices. Progesterone, total human chorionic gonadotropin, and free 8-human chorionic gonadotropin were measured in the supernatant by radioimmunoassay or enzyme immunoassays. Secreted (in the medium) and cell-bound proteases were characterized by zymography on sodium dodecyl sulfate-polyacrylamide gels containing gelatin. Cytotrophoblast cell preparations contained 12% to 34% leukocyte common antigen-positive cells before and 0% after immunopurification. Large zones of digested matrices were observed after 48 hours of culture on Matrigel or rat tail collagen but not on agarose. Cells secreted progesterone, human chorionic gonadotropin, and free β -human chorionic gonadotropin in vitro, but no difference was observed among cells grown on different matrices or between immunopurified and nonimmunopurified cells. By zymography, seven gelatin-degrading enzymes were seen in culture supernatants and five of them were present in cell lysates. The molecular weights of these proteases ranged from 59 to 230 kd. Immunopurification eliminated three of these enzymes, so they were clearly produced by bone marrow-derived cells (leukocyte common antigen positive) contaminating the cytotrophoblast cell preparation. Cells grown on Matrigel express a unique 59 kd gelatinase that was not seen in the supernatants of cells grown on other matrices. Zymography in the presence of inhibitors showed that these enzymes were neutral metalloproteinases, which might be responsible for the observed extracellular matrix degradation. (Am J OBSTET GYNECOL 1991;165:1791-1801.)

Key words: Cytotrophoblast, metalloproteinases, immunopurification, extracellular matrix

The hypothesis that the invasiveness of trophoblast is associated with its proteolytic activity was first proposed by Mossman¹ >50 years ago. Experimental evidence relating trophoblast invasiveness and proteolysis was produced much later by Blandau,² who showed that guinea pig trophoblast was capable of digesting a dried gelatin film. The same observation was also made for the rabbit blastocyst.³ The study of the role of proteinases in trophoblast implantation effectively began with the publication of Strickland et al.,⁴ who showed that the trophectoderm of mouse blastocyst produced plasminogen activator, a well-known serine protease, and

that the maximal rate of production of this enzyme was observed at the time of implantation. The importance of plasminogen activator in implantation was further documented in mutant mice with implantation deficiencies. The blastocysts of these mice attached and grew in vitro but showed a decreased invasiveness that correlated with a decreased plasminogen activator production.⁵ Human trophoblast also produces plasminogen activator.⁶

Although plasminogen activator plays a significant role in trophoblastic invasiveness, it is probably not the only protease involved in this process. Mouse blastocysts cultured on a radiolabeled matrix release radioactive peptides. This proteolytic activity seems not to be due to plasminogen activator, because digestion of the matrix still occurs in cultures depleted of plasminogen. Furthermore, in the presence of plasminogen and of ε-aminocaproic acid, a specific inhibitor of plasminogen activator, degradation of the extracellular matrix remains visible. Yagel et al. also showed that ε-aminocaproic acid blocked the invasion of basement membrane by human trophoblast. In the same study

metalloprotease inhibitors had the same effect as ε-aminocaproic acid, indicating that, besides plasmin-plasminogen activator, metalloproteases might also be important in controlling trophoblastic invasion. The same conclusion was reached in a very recent study by Librach et al., who showed that antibodies to plasminogen activator block only partially the invasion of cytotrophoblast cells into Matrigel, whereas antibodies to the 92 kd collagenase inhibit this invasion completely.

Fisher et al.10 demonstrated the presence of several metalloproteinases secreted by first-trimester cytotrophoblasts, some of which were absent or greatly reduced later in gestation. Unfortunately, bone marrowderived cells, which contaminate cytotrophoblast cell preparations and which are known to release proteases, were not eliminated by their cell purification technique. It is the purpose of our study to define more precisely the origin and nature of the proteases secreted by cytotrophoblast cell preparations. To this end care has been taken to immunopurify cytotrophoblast cells and to discard those cells of lymphomyeloid origin. We also investigated the role of cell adhesion in the induction of protease secretion and cultured immunopurified trophoblast cells on different substrata and extracellular matrices to investigate the changes in their morphologic features and secretion.

Material and methods

Preparation of trophoblast cells. First-trimester trophoblastic tissue was obtained from legal abortions between 6 and 12 weeks of gestation. All manipulations were performed under sterile conditions in a laminar flow hood. Within 15 minutes from vacuum aspiration, the products of conception were washed with sterile phosphate-buffered saline solution and the trophoblast was separated manually from other tissues under a stereomicroscope. This tissue was minced and washed twice with Hanks' balanced salt solution (Sigma, St. Louis) containing 200 U/ml penicillin and 200 µg/ml streptomycin (Hoechst, Darmstadt). The washed tissue was

then incubated at 37° C five times for 10 minutes in Hanks' balanced salt solution containing 0.25% trypsin (Difco, Detroit), antibiotics, 2.5 µg/ml amphotericin B (Gibco, Basel), 100 μg/ml gentamicin (Gibco), 500 U/ml deoxyribonuclease (Sigma), 1 mol/L magnesium sulfate (Fluka, Buchs, Switzerland), and 25 mmol/L N-[2-hydroxyethyl]piperazine-N'-[2-ethanesulfonic acid] (Hepes) (Boehringer, Mannheim, Germany). After each digestion step, the supernatant was neutralized by addition of 10% fetal bovine serum (Amimed, Birsfelden, Switzerland). The supernatants were pooled, centrifuged at 800g for 10 minutes, resuspended in the same medium without fetal bovine serum, and filtered over nylon (mesh size 100 µm). The filtered cell suspension was then submitted to a 5% to 70% discontinuous Percoll gradient according to Kliman et al.11 The fraction containing the cytotrophoblast cells (densities 1.051 to 1.065) was washed with Dulbecco's modified Eagle's medium (Gibco) containing 10% decomplemented and acid-treated fetal bovine serum. Acidtreated fetal bovine serum was obtained after decomplementation (56° C for 30 minutes) by lowering the pH to 3 with hydrochloric acid (1 mol/L) for 2 hours at room temperature and bringing it up again at pH 7.4 with sodium hydroxide (1 mol/L). The washed cells were counted in a Neubauer cell, and half the cells were incubated (1 million per milliliter) in Dulbecco's modified Eagle's medium containing 2 mmol/L L-glutamine (Gibco), 4.2 mmol/L magnesium sulfate, 25 mmol/L Hepes, 10% decomplemented and acidtreated fetal bovine serum, 1% gentamicin, 1% amphotericin B, 100 μg/ml streptomycin, and 100 U/ml penicillin (culture medium). The other half were immunopurified.

Immunopurification of cytotrophoblast cells. The washed cytotrophoblast cells (5 million in 2 ml) were incubated for 30 minutes at 4° C with 30 µl of a monoclonal antibody to leukocyte common antigen (LCA) (Dakopatts, Copenhagen). After incubation, the cells were washed with phosphate-buffered saline solution

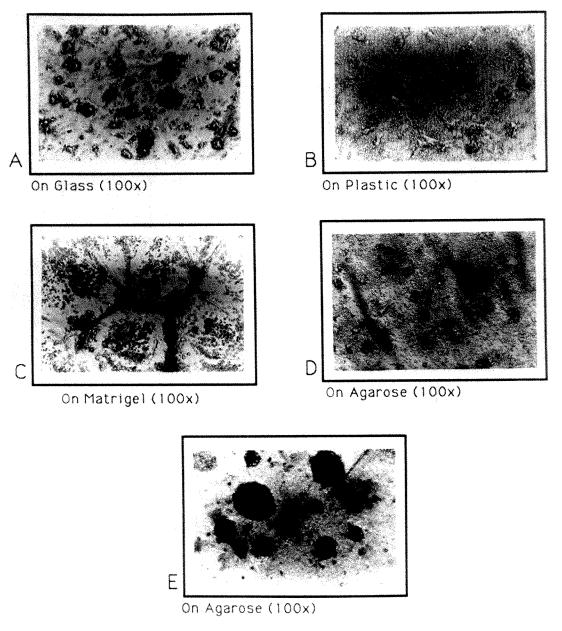

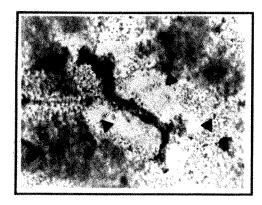

Fig. 1. Purified cytotrophoblast cells grown on glass (A), plastic (B), Matrigel (C), and agarose (D) for 3 days. E, Same as D but after 7 days of culture.

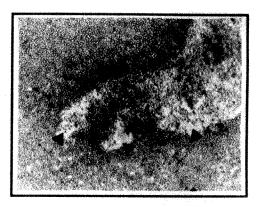

containing 0.1% bovine serum albumin (radioimmunoassay grade, Sigma). Prewashed (with phosphatebuffered saline solution and bovine serum albumin) magnetic particles coated with a second antibody (30 µl Dynabeads, Dynal, Milian Analytica, Switzerland) were then incubated with the cell suspension for 20 minutes at 4° C. A magnet was applied along the test tube to retain the particles bound to the cells expressing LCA on their surfaces. The supernatant was poured into a clean test tube, and the immunopurified cells were counted in an Neubauer cell and diluted to 1 million cells per milliliter in the culture medium.

Cell culture. Two hundred microliters of cytotro-

phoblast cells or immunopurified cytotrophoblast cells (1 million per milliliter culture medium) was incubated in 12-well tissue culture plates (Costar, Cambridge, Mass.) under a 5% carbon dioxide and 95% air atmosphere in an incubator at 37° C. The wells were precoated with 300 µl Matrigel per well (Collaborative Research, Inotech, Switzerland), 300 µl 0.5% agarose in phosphate-buffered saline solution (Agar Noble, Difco), or 300 µl rat-tail collagen (prepared as described previously).12 Uncoated wells or wells containing glass slides were also used. Every other day the cells floating in the medium were carefully returned to the wells after centrifugation, and the supernatant was divided into aliquots and immediately frozen at -20° C. At the end

On Collagen (100x)

Fig. 2. Cultures of purified cytotrophoblast cells grown on Matrigel or rat tail collagen after 7 days. Note large zones of digested matrices (arrowheads).

of the culture period (8 to 10 days), the cells were washed and lysed with 200 μ l Triton X-100 (2.5% in water) and then stored at -20° C until assayed.

Hormone assays. Total human chorionic gonadotropin (hCG) was measured in the culture supernatant with a microparticle enzyme immunoassay with a sensitivity of 1 mIU and a coefficient of variation of 3.6% (Abbott, Abbott Park, Ill.). Progesterone and free β-hCG were measured by commercially available radioimmunoassay kits (CIS, sensitivity 0.25 ng/ml, coefficient of variation 7.3%; Mediginex, sensitivity 0.04 ng/ml, coefficient of variation 5.3%, Medipro AG, Teufen, Switzerland). Results were expressed per 1 million cells as milli—international units or nanograms per milliliter.

Zymography. Proteases were visualized by zymography with a modification of the technique described by Fisher et al. 10 Briefly, 10% polyacrylamide gel in 0.1%sodium dodecyl sulfate containing 1 mg/ml gelatin (Merck, Darmstadt, Germany) or casein (Sigma) were cast at a final dimension of $80 \times 85 \times 0.8$ mm. After polymerization of the 10% gel, a 2% polyacrylamide stacking gel was cast above the previous one. Molecular weight standards (Pharmacia, Uppsala) and samples to be analyzed (30 µl) were incubated at room temperature for 5 minutes with 5 µl sample buffer (17.4% sodium dodecyl sulfate, 7% sucrose, and phenol red in water). Twenty-five microliters of the incubate was placed over the stacking gel and electrophoresis was run at 7 A for approximately 5 hours at 8° to 10° C in 25 mmol/L Tris hydrochloride containing 0.19 mol/L glycine and 0.1% sodium dodecyl sulfate, pH 8.6.

After electrophoresis, the gel was put through six 5-minute washes in 2.5% Triton X-100 (2.5% in water) and three times for 5 minutes in phosphate-buffered saline solution. The gel was then placed in phosphate-buffered saline solution, pH 7.4, containing 0.9 mmol/L calcium chloride and magnesium chloride (in

the presence or absence of protease inhibitors) and incubated overnight at room temperature on a moving platform. The next morning the gel was stained with Coomassie Brilliant Blue G250 (0.1% in 25% methanol and 10% acetic acid in water, Fluka) and destained in 5% methanol and 7.5% acetic acid in water.

Protease inhibitors used were 1 mmol/L ethylene-diaminetetraacetic acid (Fluka), 0.2 mmol/L 1,10-phenanthroline, 2 mmol/L phenylmethylsulfonylfluoride, 1 mmol/L pepstatin A, and 1 mmol/L iodoacetamide (all from Sigma).

Immunocytochemistry. Cells were centrifuged at 700g onto glass slides with a Cytospin centrifuge (IG, Geneva). They were fixed 5 minutes in acetone at -20° C, and the slides were washed twice with phosphate-buffered saline solution. Fifty microliters of phosphate-buffered saline solution and bovine serum albumin (5%) was added to the cells and incubated for 10 minutes at room temperature. The phosphate-buffered saline solution and bovine serum albumin drop was gently blotted and replaced by 50 µl of the first antibody (see text that follows). After 30 minutes the glass slides were washed twice in phosphate-buffered saline solution and the alkaline phosphatase-second antibody complex (50 µl immunoglobulin G rabbit antimouse, Dako) was added to the cells. After a 30-minute incubation the second antibody was replaced by a third antibody (alkaline phosphatase coupled with antirabbit immunoglobulin G, 50 µl, Dako) and incubated as described in the preceding text. The slides were then stained with naphthol AS-BI phosphate (Sigma), 5 mg in 50 µl N,N-dimethylformamide containing 10 mg Fast Red and 10 mg levamisole in Tris hydrochloride, 0.1 mol/L, pH 8.2 After a 5-minute incubation in a moist atmosphere, the slides were washed and counterstained with hematoxylin. The slides were evaluated under the microscope, and the results were expressed

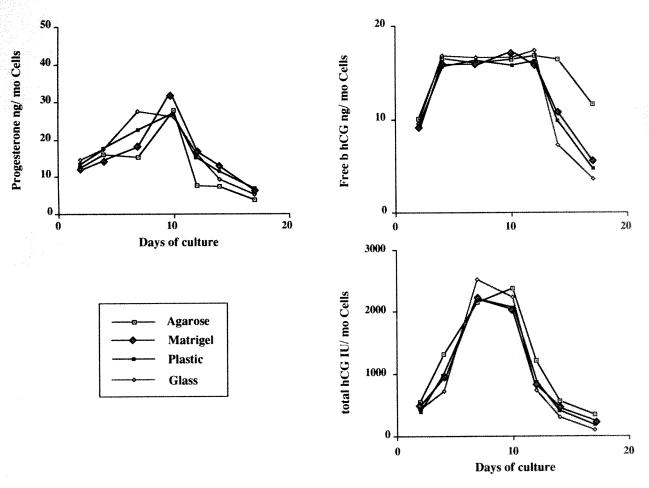

Fig. 3. Effect of matrices on hormone production by purified cytotrophoblast cells.

as the percent of positive cells per 300 total cells counted.

The first antibodies used included pregnancy-specific β₁-glycoprotein (1:50), hCG (1:100), placental lactogen (1:20), human leukocyte antigen (HLA) class I (1:50), vimentin (1:20), LCA (1:20), and factor VIII (1:20) (all from Dako), and anticytokeratin (clones AE1 and AE3, 1:50, Boehringer; clones CAM 5 and 2, Becton-Dickinson, Inotech). These last two antibodies were used as a 1:1 mixture. Negative controls were run in parallel and were obtained by replacing the first antibody with phosphate-buffered saline solution containing 5% bovine serum albumin.

Results

Immunocytochemistry. As shown in Table I, hCG-, pregnancy-specific β₁-glycoprotein-, and placental lactogen-positive mononuclear cytotrophoblast cells represented <10% of the total cell population. More than one third of the cells in the cell suspension were positive for HLA Class I antigens, indicating either an extravillous origin of trophoblastic cells or the presence of lymphomyeloid cells.

Before immunopurification only 50% to 72% of the cells were epithelial in origin and keratin positive, whereas after purification these values increased to 90% to 97%. Lymphomyeloid cells accounted for 12%to 34% before purification but became undetectable after immunopurification. No endothelial cells could be seen either before or after purification (0%, factor VIII), whereas purification did not affect the low contamination by fetal stromal cells (2% to 7% vimentin positive). Thus after immunopurification the cell suspension represented 90% to 97% cytotrophoblastic cells with a 3% to 7% contamination by fetal stromal cells (Table I).

Behavior of cells in culture. Within 12 hours of culture, mononuclear cytotrophoblast cells adhered to glass, plastic, Matrigel, or rat-tail collagen but not to agarose. The cells flattened out on these matrices and grew as small colonies of aggregated cells (Fig. 1, A and B), but on Matrigel the cells aggregated in a netlike pattern with large zones devoid of cells in the immediate vicinity of the aggregates (Fig. 1, C). After 72 hours of culture, syncytium-like structures formed on all matrices except agarose. On agarose, cells did not

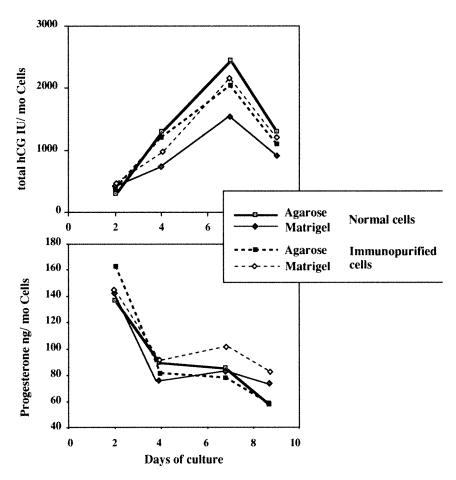

Fig. 4. Effect of immunopurification on hormone production by cultures of cytotrophoblast cells.

attach to the substrate and remained floating in the medium, where they grew as aggregates. With time the size of these aggregates increased considerably, with no evidence of attachment (Fig. 1, D and E). On both rattail collagen and Matrigel, large zones devoid of cells could be seen clearly after 3 to 4 days in culture. After the matrices in the wells were stained with Coomassie blue, the cell-free zones did not stain, showing a complete digestion of the matrix in these areas (Fig. 2, A and B).

Hormone production. Immunopurified cytotrophoblast cells (10^6 cells/ml) were cultured up to 17 days on the different matrices, and the medium was changed every other day. As shown in Fig. 3, the nature of the matrix on which the cells were cultured did not change the secretion pattern of progesterone and total or free β-hCG. Irrespective of the culture conditions, the concentrations of progesterone and total hCG increased from day 0 to day 10 and gradually decreased thereafter. The concentration of free β-hCG followed a different pattern. A plateau was reached by the fourth day of culture and lasted up to day 12 before decreasing. Here also, adhesion of the cells to the matrix (as

in glass, plastic, or Matrigel), as compared with cells that did not adhere to the matrix (as in agarose), had no effect on free β -hCG secretion. Immunopurification per se did not change the secretion of total hCG or progesterone by cytotrophoblast cells cultured on agarose or Matrigel (Fig. 4).

Protease production. Gelatin zymography, but not casein zymography, of cytotrophoblast cell supernatants after 48 hours of culture revealed seven bands of digestion ranging from 59 to 230 kd (Fig. 5); three of them (230, 94, and 64 kd) were particularly intense, whereas the other ones (197, 128, 73, and 59 kd) appeared much weaker. Only four of these seven bands (230, 128, 94, and 65 kd) were associated with the cells, because they were expressed in the zymograms of the cell lysates (Fig. 6). Two other gelatinases (197 and 59 kd) appeared only to be secreted, because they were not visible in the zymogram of the cell lysate; band 5 (73 kd) was present in the medium incubated for 48 hours in the absence of cells (Fig. 5, lane 2; Fig. 6, bottom, lane 5) and probably represented a contaminant. The 230 and 128 kd gelatinases are clearly of lymphomyeloid origin, because these bands were no

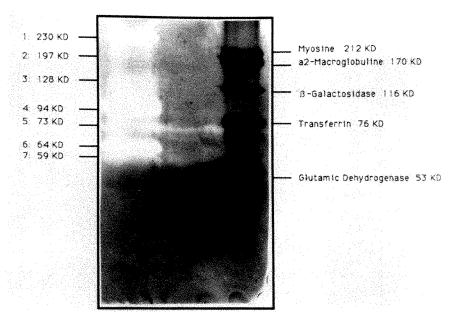

Fig. 5. Zymogram of supernatant of purified cytotrophoblast cells grown for 48 hours on Matrigel (first lane); cell-free incubation medium after 48 hours of incubation on Matrigel (second lane), and standards (third lane).

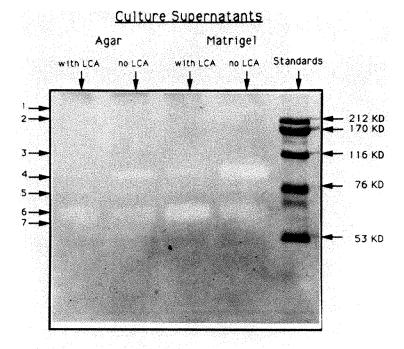

longer visible after immunopurification of the cytotrophoblast cells (Figs. 6 and 7). Immunopurification reduced the intensity of the 94 kd gelatinase, indicating its dual origin: trophoblastic and lymphomyeloid (Figs. 6 and 7), whereas the 64 kd gelatinase seemed more active after immunopurification (Figs. 6 and 7). Thus one can consider that mononuclear cytotrophoblast cells release four unique gelatinases of 197, 94, 64, and 59 kd. When compared with cells grown on agarose or plastic, cells grown on Matrigel seemed to express the 94 kd gelatinase more intensely (Fig. 7), whereas the other proteinases remained unchanged. However, this was true only when the cells were not immunopurified (Fig. 7), perhaps indicating that Matrigel might specifically activate the 94 kd gelatinase of lymphomyeloid origin. The 59 kd proteinase appeared to be induced only by collagen because it was present in the supernatants of cells grown on Matrigel and rat-tail collagen but absent when the cells were grown on agarose or plastic (Fig. 7). The pattern of expression of gelatinases secreted in the supernatants of cells grown on glass was superimposable to the pattern of cells grown on plastic, and those grown on rat-tail collagen were similar to the patterns of cells grown on Matrigel (results not shown).

As shown on Fig. 7, when the gels were incubated overnight with phosphate-buffered saline solution containing 1 mmol/L ethylenediaminetetraacetic acid, digestion bands were no longer visible. The same observation was made when ethylenediaminetetraacetic acid was replaced by 1:10 phenanthroline (results not shown). No inhibition was observed with pepstatin A or iodoacetamide. In contrast, a complete inhibition of the gelatinases was observed when divalent ions (calcium and magnesium) were absent from the gel incubation buffer.

Comment

Human placental cells isolated by enzymatic digestion and cultured in vitro are known to yield a mixed cell population.13 Contaminating cells include macrophages, fibroblasts, endothelial cells, and blood elements. Several attempts to improve the purity of trophoblast cell cultures have been proposed on the basis of physical properties,11 immunologic properties,14 or biologic properties.^{15, 16} One such technique of immunomagnetic purification was using HLA class I and II antibodies14 to remove contaminating cells (mostly macrophages and fetal stroma). Our purpose of characterizing the proteases secreted by cytotrophoblast cells prompted us to develop a technique that unequivocally eliminated known sources of extratrophoblastic proteases, such as monocytes, macrophages, and other lymphomyeloid cells.

Because extravillous cytotrophoblast cells in culture express HLA class I antigen,15 the use of an anti-HLA antibody will eliminate those cells together with those of lymphomyeloid origin. Extravillous cytotrophoblast cells represent the cells invading the uterine lining,15 thus the cells that potentially express the proteases. These considerations guided our choice in using an

Cell Lysates

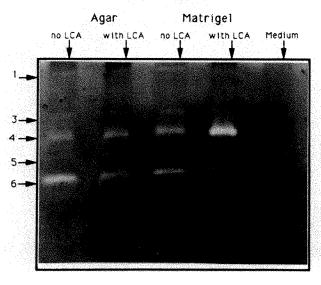

Fig. 6. Zymograms of supernatant and cell lysates of cytotrophoblast cells purified (*with LCA*) or not (*no LCA*) grown on agarose or Matrigel.

anti-LCA antibody to eliminate only lymphomyeloid cells. The technique allowed >90% isolation of cytotrophoblast cells; however, this choice had its drawbacks because fetal stromal cells still contaminated our cultures by about 5%. Very recently and independently, Librach et al. used the same antibody with a similar technique to purify their cytotrophoblast culture; they reported corresponding success.

The phenotype of the cytotrophoblast cells observed in our study corresponded to that of previous descriptions, $^{14.17\cdot19}$ with the exception that adhesion of cells to glass or plastic was not as extensive as described because only about 50% to 70% of the cells adhered. It is not known if this was due to the use of acid-treated fetal bovine serum.

Aggregates or syncytia were clearly visible on glass, plastic, collagen, and Matrigel. In contrast, no adhesion was seen on agarose where spheroid-like aggregates formed in the supernatant. No attempts were made in this study to define whether aggregates represented

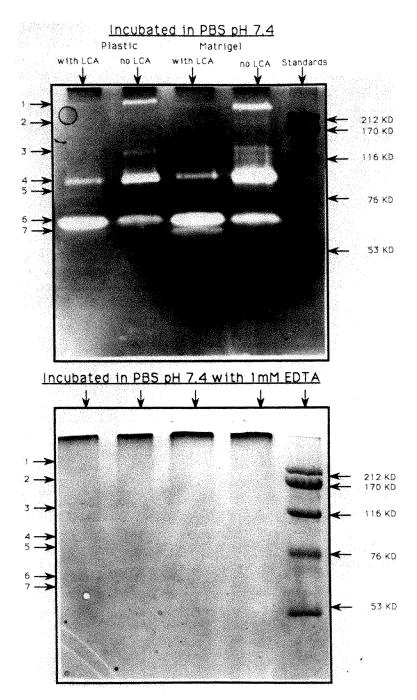

Fig. 7. Zymograms of supernatants of cytotrophoblast cells purified (with LCA) or not (no LCA) grown on Matrigel or plastic. Gels were incubated without (upper panel) or with (lower panel) ethylenediaminetetraacetic acid.

true syncytia or merely aggregated cells, because the cell boundaries were not easily visible under the inverted microscope and staining for desmoplakin as recommended18 was unsuccessful in our hands.

In agreement with other studies,20,21 the mononuclear cytotrophoblast cells produced hCG and progesterone with the pattern of production changing rapidly with the age of the placenta. This is illustrated by the differences in the secretion profiles of progesterone and hCG between Figs. 3 and 4 where 11- and 7-weekold placentas were used, respectively. The secretion of free β-subunit followed a slightly different pattern than hCG with a constant production over a period of 10 days, a finding not reported before. We observed, as already reported,22 that adhesion in itself and the nature of the matrix did not influence the endocrine activity of cytotrophoblast cells. Because adhesion of the cytotrophoblast cells seems to be a prerequisite for syncytium formation, our observation would imply that biochemical and morphologic differentiation can be uncoupled, an observation previously made by others. 22 In addition to the cells' endocrine function, the presence of four unique extracellular matrix-degrading metalloproteinases produced by cytotrophoblast cells and identified by zymography was reported by us. The molecular weights of these proteinases were approximate because their determination is influenced by the choice of markers, acrylamide concentration, and copolymerized substrate. The metalloproteinases described here correspond to those described by Fisher et al.,10 who demonstrated the presence of five metalloproteinases (68 to >200 kd) secreted by first-trimester trophoblast cells. However, in their culture system the lymphomyeloid cells were not eliminated. In a very recent article from the same group9 they also used an LCA-based immunopurification technique but did not show any zymograms. Although the four cytotrophoblast-specific metalloproteinases (197, 94, 64, and 59 kd) described here were not influenced by adhesion of the cells to the substrate, depending on the nature of the substrate, regulatory effects were seen. The 59 kd gelatinases were observed only when cells were cultured on substrata containing type I collagen, and the 94 kd gelatinase was much more expressed when the cells were grown on Matrigel. This last observation was true only for nonimmunopurified cells, indicating either that Matrigel specifically stimulates the 94 kd gelatinase of bone marrow-derived cells or that a matrigel-induced paracrine factor of cytotrophoblastic origin regulates the nontrophoblastic enzyme. That some of the described proteases were active in the culture is indicated by the fact that the cells degraded both matrigel and collagen, an observation previously made by others. 9, 10, 19 This degradative behavior seems to be due essentially to the 92 kd collagenase.9 The fact that the gelatinases were active in culture is of importance because proteases are secreted as proenzymes and sodium dodecyl sulfate (used for zymography) is known to artifactually activate the proenzymes.

Although the nature of the described cytotrophoblastic metalloproteinases has not been defined, it is interesting to note that neutral metalloproteinases of the same molecular weights have been described in other cell cultures. Corneal fibroblasts,²³ alveolar macrophages,²⁴ and embryonic cells²⁵ all express a 92, 67, and 51 kd neutral metalloprotease recognized as the 92 kd collagenase type IV, the 72 kd collagenase (which migrates at 64 to 67 kd in copolymerized gels), and stromelysin (faint band on gelatin at 51 kd), respec-

tively. These enzymes belong to the so-called matrix metalloproteinase family. These proteases are classified as MMP-1, that cleaves collagen types I, II, and III, called interstitial collagenases (52, 64 kd); MMP-2 or gelatinases, that degrade collagen types IV and V (92 kd) and collagen types IV, V, VII, and fibronectin (67 kd); and MMP-3, called proteoglycanases or stromelysins which cleave proteoglycans, type IV collagen, casein, and fibronectin (51 kd). More recently, similar matrix metalloproteinases have been described in hepatocytes²⁶ and human sertoli cells.²⁷ Thus cytotrophoblasts express an array of matrix metalloproteinases similar to many other cells. But in contrast to these other cells, cytotrophoblasts have an invasive phenotype. Taking into account the capacity of matrix metalloproteinases to digest basement membrane and extracellular matrix components, one must suppose that the regulation of activity is a phenomenon specific to each cell type.

We thank Mrs. L. Haenggeli for her skillful assistance.

Improvement of in vitro fertilization and early embryo development in mice by coculture with human fallopian tube epithelium

Jeffrey M. Goldberg, MD, Essam Al-Dein M. Khalifa, MD, Chad I. Friedman, MD, and Moon H. Kim, MD

Columbus, Ohio

Coculturing one- and two-cell embryos with various cell lines has been shown to overcome species-specific developmental blocks and to improve blastocyst transformation rates. The objective of this study was to assess whether human fallopian tube epithelium organ explants influence in vitro fertilization and subsequent early embryo development in a murine model. Fertilization, blastocyst transformation, and blastocyst expansion and hatching rates were significantly higher in the coculture group when compared with rates for culture in standard media or media conditioned by human tubal explant cultures. The results from conditioned and unconditioned media were not significantly different. (AM J OBSTET GYNECOL 1991;165:1802-5.)

Key words: Fallopian tube, coculture, in vitro fertilization, embryo development, mouse

The birth of the first baby conceived by means of in vitro fertilization and embryo transfer established that the fallopian tube was not essential for reproduction. As a result research interest in the fallopian tube waned as shown by a reduction in the number of manuscripts in the clinical literature. During this time much attention was focused on methods of improving the low pregnancy rates achieved with in vitro fertilization and embryo transfer. In spite of an enormous volume of published literature resulting from these efforts and more than a decade of clinical experience worldwide, the pregnancy rates remain disappointing.

In addition to its transport function, the fallopian tube provides a unique environment for sperm capacitation, fertilization, and early embryo development. Because this environment is very poorly characterized, it cannot be artificially duplicated in vitro. Animal studies have revealed that preimplantation embryo development in vitro is delayed when compared with development in vivo, and culturing embryos in vitro is hampered by species-specific "blocks" to development. Also, clinical pregnancy rates with in vitro fertilization and embryo transfer are generally lower than those of gamete and zygote intrafallopian transfer, which deliver the gametes or early preimplantation embryos, respectively, into the fallopian tubes. These obser-

vations suggest that the fallopian tube contributes something that is missing in vitro.

Studies with several mammalian species have shown that early embryo development is improved by coculture with various cell lines: fibroblasts, Vero cells, cumulus cells, trophoblastic vesicles, and oviductal epithelium. Studies comparing coculture of the oviduct with that of other cell lines demonstrated the superiority of the oviduct; this implies a tissue-specific benefit. Coculturing human preimplantation embryos with fibroblasts, S. E. Vero cells, To and fallopian tube epithelial cell suspensions that of the standard culture system.

Those studies consistently documented facilitated in vitro development of early preimplantation embryos with coculture. There are no studies to date that analyze whether coculture also may increase fertilization rates in vitro. As noted, human tubal epithelial cell suspension cocultures augmented human development of pronuclear embryos to the blastocyst stage. Human fallopian tube epithelial monolayers also yielded significantly higher blastocyst rates from two-cell mouse embryos than media alone. No data are available regarding the utility of human fallopian tube epithelial organ explants in coculture. This study was designed to address these questions by means of a murine in vitro fertilization model.

Material and methods

Fallopian tube culture. Human fallopian tube epithelial organ explants were established as previously described.¹³ The ampullary segments of normal fallopian tubes were obtained at the time of hysterectomy

Table I. Fertilization, blastocyst transformation, and blastocyst expansion-hatching rates from two-cell embryos

	Fertilization	Blastocyst transformation	Expanded or hatched	
Control Conditioned	70.5 ± 8.5 70.5 ± 9.3	29.5 ± 11.6 27.4 ± 8.5	4.4 ± 4.6 9.7 ± 10.2

for benign gynecologic indications in women of reproductive age. The specimens were transported to the laboratory in Dulbecco's modified Eagle's medium (Gibco, Grand Island, N.Y.) at 4° C. The cultures were initiated within 1 hour after excision. The tubes were opened longitudinally with fine dissecting scissors. Strips of the luminal epithelium were excised with scissors and sectioned into segments of 3 mm². These were then washed three times in phosphate-buffered saline solution (Irvine Scientific, Santa Ana, Calif.) before being placed into plastic Petri dishes that were 9 cm in diameter with 5 ml of high-glucose Dulbecco's modified Eagle's medium (25 mmol/L glucose) supplemented with 2.5% fetal bovine serum (Gibco), penicillin, and streptomycin. There were approximately 20 to 25 explants per dish. The epithelial nature and viability of the tissue were confirmed by the observation of vigorous ciliary beating by means of phase-contrast microscopy at culture initiation and at each change of media. The cultures were maintained in a 37° C incubator with 5% carbon dioxide and 95% humidity. The medium was replaced daily. Conditioned medium was collected at the time of change. Explants and conditioned media were used within 7 days after the culture was established.

Murine in vitro fertilization. Female CB6F1 mice (Charles River, Wilmington, Mass.) that were between 6 and 8 weeks old were induced to superovulate with 7.5 IU pregnant mare serum gonadotropin administered intraperitoneally; this was followed by the intraperitoneal administration of 7.5 IU human chorionic gonadotropin 48 hours later. The mice were killed by cervical dislocation 15 hours after human chorionic gonadotropin administration, and the oviducts were excised. The cumulus masses were dissected from the oviducts with tuberculin needles in 2.5 ml phosphatebuffered saline solution. The cumulus masses were pooled in high-glucose Dulbecco's modified Eagle's medium with 1% bovine serum albumin (insemination media, Irvine Scientific) and were then randomly allocated to the coculture group or to the conditioned or unconditioned media group.

Mature CB6F1 male mice were killed by cervical dislocation, and both epididymides were excised. Sperm was obtained by compressing the epididymides in 0.5

ml in insemination medium, and a motile sperm concentration was determined with a Makler chamber (Sefi-Medical Instruments, Ltd., Haifa). The sperm was incubated for 1 hour at 37° C before insemination. Insemination was performed with approximately 500,000 motile sperm in a center well dish with approximately 20 oocytes in 1 ml of insemination medium. A single epithelial explant was placed with the gametes in the coculture group. The conditioned media group consisted of a 1:1 mixture of conditioned medium and unconditioned medium. The dishes were maintained in an incubator at 37° C with 5% carbon dioxide. Afer 6 hours the oocytes were transferred to high-glucose Dulbecco's modified Eagle's medium with 0.5% bovine serum albumin (growth medium). The epithelial explant was transferred with the oocytes in the coculture group. Half the medium in this group was replaced every 48 hours. The oocytes or embryos were not in physical contact with the explants. In the conditioned medium group, growth medium was mixed 1:1 with conditioned medium.

The oocytes were observed under a dissecting microscope every 24 hours for the 5 days after insemination. Fertilization was defined as cell division 24 and 48 hours after insemination. Blastocyst transformation, expansion, and hatching were calculated from the twocell stage. Statistical analysis was performed by analysis of variance with repeated measures; the Student-Newman-Keuls test was used for post hoc comparisons.

Results

Thirteen trials were run in duplicate with 1528 oocytes: 505 in the control group, 472 in the conditioned medium group, and 551 in the coculture group. All fallopian tube specimens were obtained during the proliferative phase as confirmed by endometrial histologic studies. Fertilization and embryo development rates are shown in Table I. Fertilization rates were significantly higher in the coculture group than in the control or conditioned medium groups, which had identical rates. Blastocyst transformation and subsequent full expansion and hatching rates were very significantly increased in the coculture group. The differences between the control and conditioned medium groups were not statistically significant.

Comment

Our data are consistent with those in the published literature that report improved early embryo development in coculture as a benefit that is not species specific. This is the first study to assess human fallopian tube epithelial organ explants in coculture. Human fallopian tube epithelial monolayers and cell suspensions in coculture have been shown to be effective, in spite of the fact that they lack ciliated cells. 11, 12, 14, 15 Also, there are no data regarding whether they are capable of secretory function in vitro. In contrast, secretory function has been documented in human tubal explants, 16, 17 which maintain their normal histologic architecture in addition to vigorous ciliary beating.13 Also the method used to establish the explant cultures is much simpler than that for epithelial monolayers and cell suspensions.

We found no differences between the conditioned medium and control groups. Conditioned medium from fibroblasts18, 19 or oviductal monolayers6, 20, 21 did not improve embryo development, although coculture did. It was suggested that cell-to-embryo contact enhances embryo development in vitro.19 In our study there was no physical contact between the oocytes-embryos and the explants. The beneficial effects of the coculture may result from the removal of a detrimental factor or factors from the medium, an alteration in oxygen tension, and/or the secretion of a labile product that does not retain its activity in the conditioned medium. In other studies, however, conditioned medium from oviductal monolayers12, 22 and from trophoblastic vesicles28 did yield improved embryo development rates, which suggests that the effect may have been mediated by a metabolite or secretory product.

In the almost 30-year history of the use of embryo coculture, the possibility of improving fertilization rates in vitro by coculture has not been previously investigated. Our findings confirming this hypothesis have obvious potential applications to the animal husbandry industry, as well as to clinical in vitro fertilization and embryo transfer. Because we obtained the oocytes from the oviducts, it is possible that the higher fertilization rate in vitro with coculture was due to enhanced sperm function. Recently, it has been shown that sperm motility and fertilizing capacity may be maintained and that hyperactivated motility may be induced by the endosalpingeal epithelium.24 Lippes and Wagh25 reported that fallopian tube glycoproteins bind to human sperm. It may be anticipated that results with clinical in vitro fertilization and embryo transfer could be even more impressive, because this method would use follicular oocytes that have not had the potential benefit of residing within the fallopian tubes. Studies with several mammalian species demonstrated that oocytes incorporate oviductal glycoproteins.26-29 Yang and

Yanagimachi²⁹ reported that hamster oviductal oocytes were physically altered when compared with ovarian oocytes. The former had a greater percentage of acrosomal sperm on the zona surface and were more rapidly penetrated by sperm. Also, in studies in which cocultured embryos were transferred to pseudopregnant recipients, higher implantation and pregnancy rates were noted. As 9 We hope that the apparent disparity between in vitro fertilization and embryo transfer and gamete intrafallopian transfer pregnancy rates can be reduced by more closely simulating the fallopian tube environment in vitro with the addition of a tubal epithelial explant to the culture system.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Comparison of intermittent and continuous use of a gonadotropin-releasing hormone antagonist (Nal-Glu) in in vitro fertilization cycles: A preliminary report

Denise L. Cassidenti, MD, Mark V. Sauer, MD, Richard J. Paulson, MD, Edward C. Ditkoff, MD, Jean Rivier, PhD, Samuel S.C. Yen, MD, DSc, and Rogerio A. Lobo, MD

Los Angeles, California

The agonistic effect of the gonadotropin-releasing hormone agonist often necessitates an extended period of treatment, resulting in a longer treatment cycle and increased cost. We have evaluated the intermittent use of a gonadotropin-releasing hormone antagonist, Nal-Glu, and have designed a new, simplified protocol for its use in in vitro fertilization. Seven women who had previously undergone treatment with leuprolide acetate and human menopausal gonadotropins were treated with Nal-Glu. Leuprolide acetate, 1 mg/day subcutaneously, was administered in the midluteal phase until down regulation was achieved (estradiol <30 pg/ml). Human menopausal gonadotropins, three to four ampules per day intramuscularly, was administered in conjunction with 500 µg subcutaneous leuprolide acetate. In the treatment cycles Nal-Glu (50 µg/kg/day) was administered intramuscularly on cycle day 1 or 2 for 3 days to achieve down regulation. Human menopausal gonadotropins, three to four ampules intramuscularly, was then administered daily without the antagonist. Nal-Glu was resumed when the follicles reached 14 to 16 mm and was continued until the day of human chorionic gonadotropin administration. Compared with leuprolide acetate-human menopausal gonadotropins cycles, the days required for down-regulation with Nal-Glu were significantly shortened (20.6 \pm 4.1 vs 1.6 \pm 0.3 days, p < 0.001), as was total cycle length $(31.3 \pm 5.8 \text{ vs } 11.0 \pm 1.0 \text{ days}, p < 0.01)$. The mean number of days of treatment with human menopausal gonadotropins, the mean number of ampules of human menopausal gonadotropins, peak estradiol levels, the number of oocytes, and the percent of oocytes fertilized were not statistically different. No luteinizing hormone surges were detected with Nal-Glu in serum or urine. Nal-Glu was well tolerated, and five pregnancies have resulted. We conclude that intermittent administration of Nal-Glu is highly effective in achieving down-regulation and blocking spontaneous luteinizing hormone surges. Compared with leuprolide acetate-human menopausal gonadotropins cycles, an equally high oocyte and embryo yield may be anticipated. This new protocol substantially decreases cycle length and increases patient convenience. (AM J OBSTET GYNECOL 1991;165:1806-10.)

Key words: Gonadotropin-releasing hormone agonist, gonadotropin-releasing hormone antagonist, Nal-Glu, in vitro fertilization

The gonadotropin-releasing hormone (GnRH) agonist has been used extensively for down-regulation before ovarian stimulation, to enhance follicle selection and prevent premature luteinization and luteinizing hormone (LH) surges in patients undergoing controlled ovarian hyperstimulation for in vitro fertilization (IVF). Because of the successful experience in IVF with the GnRH agonist, its use has become almost rou-

Presented in part at the Thirty-eighth Annual Meeting of the Society for Gynecologic Investigation, San Antonio, Texas, March 20-23, 1991

Reprint requests: Rogerio A. Lobo, MD, LAC + USC Medical Center, Women's Hospital, Room 1M2, 1240 N. Mission Road, Los Angeles, CA 90033. 6/6/32684 tine.^{2, 3} However, several disadvantages are inherent with its use. An extended treatment period results from the additional 2 to 3 weeks required for down-regulation to occur.⁴ In addition, the initial agonistic effect has led to occasional ovarian cyst formation,^{5, 6} and an increased requirement for gonadotropins^{7, 8} has led to increased costs with its use.

The GnRH antagonist, on the other hand, achieves down regulation rapidly without exerting an agonistic effect and therefore potentially could reduce or eliminate some of these disadvantages of the GnRH agonist. 9. 10 However, histamine allergic-type reactions with several antagonists have precluded their clinical use. Recently, however, [Ac-D-Nal¹, D-4-Cl-Phe², D-Pal³, Arg⁵, D-Glu(AA)⁶, D-Ala¹⁰]GnRH (Nal-Glu) has been used successfully in women without any significant side effects. 11 Frydman et al. 12 have previously demonstrated the effectiveness of Nal-Glu in preventing spon-

taneous LH surges during controlled ovarian hyperstimulation in normal women. We therefore devised a new protocol for using Nal-Glu in IVF to enhance patient acceptance and achieve the same benefits of GnRH agonists while minimizing its disadvantages. We hypothesized that Nal-Glu may need to be administered only intermittently: an initial treatment to achieve down-regulation, then again at midcycle to prevent premature luteinization and LH surges.

Material and methods

Seven women undergoing ovarian hyperstimulation for IVF or gamete donation were studied. The mean age of the patients was 35.1 ± 1.2 years (range 32 to 40 years). All women had previously undergone an IVF cycle with leuprolide acetate and human menopausal gonadotropins. Therefore each woman served as her own control for comparison of the two hyperstimulation protocols.

In the control cycle patients received leuprolide acetate (Lupron, TAP Pharmaceuticals, Deerfield, Ill.), I mg subcutaneously daily beginning in the midluteal phase of the previous menstrual cycle for 14 days or until down-regulation was achieved (estradiol <30 pg/ml). Human menopausal gonadotropins (hMG) (Pergonal, Serono Laboratories, Norwell, Mass.), three to four ampules per day intramuscularly, was begun after down-regulation. Leuprolide acetate was decreased to 500 µg subcutaneously and administered in conjunction with human menopausal gonadotropins until human chorionic gonadotropin (hCG), 10,000 IU, was administered.

In the treatment cycle, patients received the GnRH antagonist Nal-Glu, 50 µg/kg/day intramuscularly, beginning on cycle day 1 or 2 for 3 days or until down regulation was achieved (estradiol <30 pg/ml). Nal-Glu was obtained from the Salk Institute in collaboration with S.S.C. Yen, MD, DSc, University of California, San Diego, La Jolla, Calif. Nal-Glu was then discontinued, and the usual dose of hMG (three to four ampules per day) was administered intramuscularly. When the largest follicles reached 14 to 16 mm, Nal-Glu was restarted and administered daily in conjunction with hMG until hCG was administered.

The protocol for ovarian stimulation and monitoring of each cycle was identical. Transvaginal ultrasonography with a General Electric 3200 was used to monitor follicular growth in conjunction with serum estradiol levels. hCG, 10,000 IU, was administered when the lead follicles reached 20 mm in both leuprolide acetate and Nal-Glu cycles. Patients in the Nal-Glu group collected urine specimens every 4 hours on the day of hCG, before its administration. The specimens were analyzed for the presence of LH with a commercially available enzyme-linked immunoassay (Ovuquick, Monoclonal Antibodies, Mountain View, Calif.). Transvaginally guided follicle aspiration was performed 36 hours after hCG administration. Embryos were replaced transcervically 48 hours after aspiration, into the patient in the case of IVF or into an artificially cycled agonadal recipient for ovum donation. Progesterone supplementation was provided in the form of progesterone in oil, 25 mg intramuscularly, daily in all IVF patients. Donor ovum recipients received hormonal replacement as previously described.18 Serum β-hCG levels were determined 9 and 14 days after embryo transfer. Pregnancy was confirmed by transvaginal ultrasonography.

Blood samples were centrifuged and the sera were extracted and then analyzed for estradiol on the same day by rapid radioimmunoassay (Pantex, Santa Monica, Calif.). Serum samples were then frozen and stored at -20° C until analyzed for LH in a previously validated assay by double-antibody radioimmunoassay.14 Intraassay and interassay coefficients of variation for the estradiol and LH assays did not exceed 7% and 12%, respectively.

Statistical analyses were carried out with the Student t test (paired and unpaired). All values are reported as mean ± SE.

Results

With the use of Nal-Glu, the amount of time required for down-regulation (estradiol, <30 pg/ml) significantly decreased compared with leuprolide acetate-human menopausal gonadotropins cycles (1.6 \pm 0.3, range I to 3 days vs 20.1 ± 4.1 , range 14 to 47 days, p < 0.001) (Fig. 1). Baseline levels of estradiol were significantly higher with leuprolide acetate-human menopausal gonadotropins (120 ± 10 pg/ml) than with Nal-Glu-human menopausal gonadotropins (57.4 ± 10.5 pg/ml, p < 0.05). This difference is reflective of our protocol, where leuprolide acetate is begun in the midluteal phase. Serum estradiol levels after down-regulation with either GnRH agonist or Nal-Glu were comparable.

Serum LH baseline levels were not significantly different in the leuprolide acetate-human menopausal gonadotropins group (11.9 ± 3.4 mIU/ml) compared with the Nal-Glu-human menopausal gonadotropins group (13.7 \pm 1.6 mIU/ml) (Fig. 2). After down-regulation with Nal-Glu, serum LH levels were significantly lower than at baseline (p < 0.01). In addition, serum LH in the Nal-Glu-human menopausal gonadotropins group after down-regulation (6.4 ± 0.9 mIU/ml) was significantly lower than serum LH values of the leuprolide acetate-human menopausal gonadotropins group (10.9 \pm 1.7 mIU/ml, p < 0.05).

In a comparison of serum LH levels in the two groups on the day of hCG administration, in the Nal-Gluhuman menopausal gonadotropins group serum LH was 9.7 ± 0.9 mIU/ml, which was significantly lower than with leuprolide acetate-human menopausal gonadotropins (14.9 \pm 1.5 mIU/ml, p < 0.01). A signif-

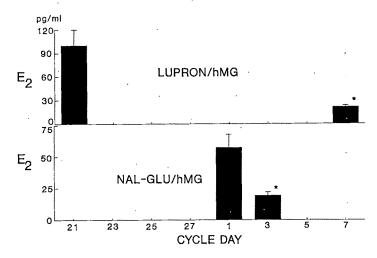

Fig. 1. Comparison of length of time needed for estradiol down-regulation between leuprolide acetate—human menopausal gonadotropins and Nal-Glu—human menopausal gonadotropins regimens. Asterisks, Significant differences between estradiol levels at baseline and at down-regulation (p < 0.05). Estradiol levels at time of down-regulation are not different in two groups.

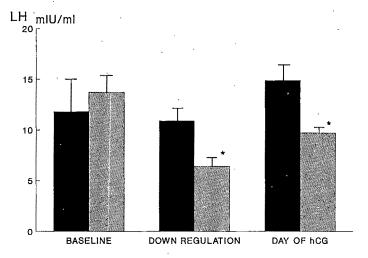

Fig. 2. Comparison of LH levels between leuprolide acetate—human menopausal gonadotropins (solid bars) and Nal-Glu—human menopausal gonadotropins (striped bars) cycles at baseline, after down-regulation, and on day of hCG administration. LH decreased significantly with Nal-Glu—human menopausal gonadotropins (p < 0.05). Asterisks, Differences between two groups at down-regulation (p < 0.05) and on day of hCG (p < 0.01).

icant increase in LH occurred in the leuprolide acetate—human menopausal gonadotropins group during human menopausal gonadotropins stimulation in spite of continued leuprolide acetate administration (serum LH was 10.9 ± 1.7 mIU/ml after down-regulation and 14.9 ± 1.5 mIU/ml on the day of hCG administration, p < 0.05). However, an increase was not observed in Nal-Glu cycles in spite of the fact that Nal-Glu was not administered during this time.

Table I compares the results of treatment in the leuprolide acetate-human menopausal gonadotropins and Nal-Glu-human menopausal gonadotropins groups. The mean cycle length in the Nal-Glu-human menopausal gonadotropins group was significantly shorter than in leuprolide acetate—human menopausal gonadotropins cycles (11.0 \pm 1.0, range 8 to 14 days vs 31.3 \pm 5.8, range 17 to 54 days, p < 0.01). The mean total days on treatment was significantly decreased with the use of intermittent Nal-Glu (6.7 \pm 0.42 vs 31.3 \pm 5.8 days, p < 0.01). The mean number of days of human menopausal gonadotropins treatment (8.3 \pm 0.4 vs 8.7 \pm 0.6), mean number of ampules of human menopausal gonadotropins (29.9 \pm 2.1 vs 31.3 \pm 2.7), peak estradiol levels (2485 \pm 300 vs 2250 \pm 245 pg/ml), number of oocytes obtained (13.9 \pm 3.0 vs 11.9 \pm 1.2), and percent of oocytes fer-

tilized (53.9% \pm 11.6% vs 60.3% \pm 10.2%) were not significantly different between the two groups. Three pregnancies have resulted from treatment in the leuprolide acetate-human menopausal gonadotropins group, and five pregnancies have occurred in the Nal-Glu-human menopausal gonadotropins group.

Nal-Glu was well tolerated. No complaints of hypoestrogenism (i.e., hot flushes) were observed. Two women developed a histamine reaction resulting in a pruritic allergic wheal. These symptoms resolved within 1 day after cessation of Nal-Glu.

Comment

The administration of a GnRH agonist daily initially stimulates and then suppresses pituitary-ovarian function through a desensitization of the pituitary.15 The total time required for down-regulation has been shown to be approximately 14 days.4 With the administration of Nal-Glu, the time required to achieve downregulation is significantly reduced. Acting as a competitive inhibitor of gonadotropin-releasing hormone, Nal-Glu lacks an agonistic effect and directly blocks the pituitary, preventing hypothalamic GnRH-induced gonadotropin release.16 When Nal-Glu is used as an adjunct for stimulation with gonadotropins, down-regulation is achieved more readily and the total cycle length is decreased because the agonistic phase is eliminated. This substantially increases patient convenience.

The administration of Nal-Glu resulted in significantly lower levels of LH after down-regulation, in comparison with treatment with the agonist leuprolide acetate. The rationale behind the down-regulation of patients with Nal-Glu was to better compare these cycles with our established hyperstimulation protocol with leuprolide acetate-human menopausal gonadotropins. Serum LH levels declined within 24 hours of Nal-Glu administration, whereas no significant decrease in LH levels was noted during down-regulation with leuprolide acetate. This illustrates the more effective inhibition of gonadotropin release by the antagonist versus the agonist. Our data therefore support the notion that Nal-Glu provides a short, convenient regimen for use in IVF, accomplishing acute and rapid pituitary down regulation, as well as preventing premature luteinization and LH surges. In addition, the need for continuous hypothalamic-pituitary suppression appears not to be essential as demonstrated by our protocol. Intermittent administration of the GnRH antagonist (initially and at midcycle) may be all that is necessary for prevention of premature luteinization and LH surges.

On the day of hCG administration, significant suppression of LH by Nal-Glu was evident when compared with the cycles where leuprolide acetate was administered. Patients treated with leuprolide acetate showed a significant increase in serum LH levels as a result of ovarian hyperstimulation, in spite of continuous leuprolide acetate administration. However, the midcycle LH surge was inhibited. Whether this small increment in LH, which occurred with stimulation in leuprolide acetate cycles, is of significance in terms of follicular luteinization and oocyte quality is unknown at present. Although the wide success achieved with leuprolide acetate in IVF cycles speaks for itself, elevated LH levels have been implicated in failures in IVF because of poor oocyte quality and in early abortion.17, 18

In this preliminary study we were unable to find a difference between the two protocols in the number of days of human menopausal gonadotropins treatment and in the number of ampules required for ovarian stimulation. Previous studies7,8 have shown an increase in the number of ampules required when down-regulation with GnRH agonist is used. This has been suggested to be due to either the suppressed levels of endogenous bioactive LH and follicle-stimulating hormone by the GnRH agonist, resulting in an increased need of exogenous stimulation for follicle recruitment, or a direct inhibiting effect of the agonist on the ovary. Our data showed no differences in the requirement for gonadotropins with leuprolide acetate or Nal-Glu. While it is possible that Nal-Glu may have resulted in a decreased requirement of gonadotropins with larger patient groups, our data are more supportive of the first notion, that profound inhibition of endogenous gonadotropins results in a greater requirement of exogenous gonadotropins.

Pregnancies resulted from both treatment cycles. In the leuprolide acetate—human menopausal gonadotropins cycles, three pregnancies occurred (two from IVF and one from donor oocytes after treatment with leuprolide acetate—human menopausal gonadotropins). However, no pregnancy is currently in progress. In the Nal-Glu—human menopausal gonadotropins cycles, five pregnancies resulted (two from IVF and three from donor oocytes after Nal-Glu—human menopausal gonadotropins). Of these, the three recipients of donor oocytes are currently pregnant. Although our numbers are too small to demonstrate a difference, or lack of one, in terms of pregnancy rates with the two treatments, Nal-Glu cycles were clearly able to provide healthy oocytes that could result in pregnancy.

The ease and efficiency of the use of the GnRH antagonist Nal-Glu for down-regulation and in preventing the midcycle LH surge during ovarian hyperstimulation for IVF has been demonstrated. Although our study population is small, this preliminary study suggests that Nal-Glu does not produce any detrimental effects and is as effective as other currently used hyperstimulation regimens.

The gonadotropin-releasing hormone antagonist (Nal-Glu) acutely blocks the luteinizing hormone surge but allows for resumption of folliculogenesis in normal women

The gonadotropin-releasing hormone antagonist offers several advantages over the use of the agonist and allows several physiologic questions to be addressed. In this study, we evaluated the ability of Nal-Glu to acutely inhibit the luteinizing hormone surge and prevent ovulation. We also assessed whether recovery of the follicle would be possible after several days of gonadotropin deprivation and estradiol decrement. Eight normal ovulatory women were randomized to control or Nal-Glu-treated cycles (50 µg/kg intramuscularly) for 3 to 4 days. Monitoring was carried out with daily vaginal ultrasonographic scans and serum estradiol levels and twice-daily serum luteinizing and follicle-stimulating hormone levels. Nal-Glu acutely inhibited the luteinizing hormone surge and ovulation, even when administered as late as the onset of the luteinizing hormone surge. Evidence was provided that spontaneous follicular rescue recurred in eight of 10 cycles after 3 to 4 days of Nal-Glu administration. Although an estradiol to follicular size dissociation occurred with Nal-Glu, subsequent ovulation occurred in 5.1 ± 0.6 days after the last Nal-Glu dose. The decrement in estradiol after Nal-Glu administration correlated negatively with the days required for subsequent ovulation to occur (r = 0.77, p < 0.05). The subsequent luteal phase also was normal in terms of length and progesterone levels. These data confirm the potency and efficacy of Nal-Glu in acutely inhibiting gonadotropins and extends our knowledge on the physiologic characteristics of the dominant follicle. (Am J OBSTET GYNECOL 1991;165:1811-7.)

Key words: Nal-Glu, gonadotropin-releasing hormone antagonist, follicle growth, ovulation inhibition

Use of the gonadotropin-releasing hormone (GnRH) agonist has become commonplace in the treatment of several reproductive disorders and has been useful as an adjunctive treatment for ovarian stimulation with gonadotropins. In ovarian stimulation for in vitro fertilization, its use has been helpful in preventing premature luteinization and premature luteinizing hormone (LH) surges. By virtue of ovarian suppression before gonadotropin stimulation, use of GnRH agonist has resulted in a greater number of oocytes obtained when used in cycles in in vitro fertilization.1,2

With the GnRH agonist, however, the goal of down regulation may require 1 to 3 weeks to achieve.3 It is also associated with an initial agonistic (stimulatory) phase that may lead to ovarian cyst formation. With the use of GnRH antagonists, however, these disad-

Presented in part at the Thirty-eighth Annual Meeting of the Society

pin levels and does not exhibit an agonistic effect.4 However, because of relatively low potency and the induction of histamine release by mast cells, the clinical application of GnRH antagonists has been limited.5 Nal-Glu [Ac-D-Nal¹, D-4-Cl-Phe², D-Pal³, Arg⁵, D-Glu (AA)⁶, D-Ala10], a GnRH antagonist that is several times more potent than those previously reported and has low mast cell secretagogue activity,6 has been developed7 and tested clinically.8-16 Nal-Glu is a decapeptide similar to GnRH except for substitutions of amino acids at positions 1, 2, 3, 4, 5, 6, and 10. A naphthylalanine residue is at position 1, a 4-Cl-phenylalanine at position 2, phenylalanine-ammonia-lyase at position 3, arginine residue at position 5, D-4-(p-methoxybenzoyl)-2 aminobutyric acid at position 6 and alanine at position 10. The ability of Nal-Glu to acutely inhibit gonadotropin secretion has allowed several physiologic questions to be answered.

vantages may be overcome, because the antagonist in-

duces an immediate decrease in circulating gonadotro-

Our purpose in this study was to determine whether the antagonist Nal-Glu is able to acutely inhibit the LH surge and prevent ovulation when administered only at midcycle to normal women. Furthermore, we sought to determine if follicle rescue may occur with gonad-

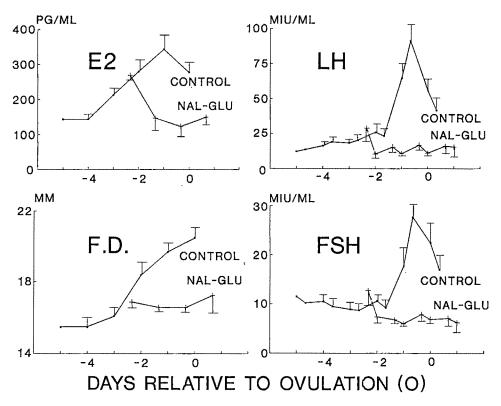

Fig. 1. Mean \pm SE of estradiol (E2), LH, FSH, and follicular diameters (F.D.) at midcycle in eight ovulatory women monitored during control cycles, compared with their data in Nal-Glu cycles.

otropin recovery after several days of gonadotropin deprivation and estradiol decrement. If Nal-Glu were to be successful in acutely inhibiting the spontaneous LH surge, it would prove to be valuable as an adjunct for induction of ovulation with menotropins.

Material and methods

Subjects. Eight normal, cycling women aged 22 to 35 years (31.4 ± 6) were studied. All women were ovulatory with documented cycle lengths of 25 to 31 days and were using a mechanical form of contraception at the time of enrollment. The subjects were in good health and received no medications during the study period. No woman had received any hormonal therapy for at least 2 months before the study. The project was approved by our institutional review board, and written informed consent was obtained from each subject.

Protocol. All eight women were studied during two consecutive cycles consisting of a control and a treatment cycle, the sequence of which was randomly determined. The control cycle consisted of daily transvaginal ultrasonography performed by the same individual, beginning once a patient's lead follicle had reached 16 mm. Follicular diameters were taken to be the maximum diameter of several measurements carried out for each follicle. Ultrasonographic scanning continued daily until each follicle was seen to rupture. The Siemens Sonoline SLI model with a 5.0 MHz vag-

inal probe was used for ultrasonographic monitoring. Blood samples were obtained twice daily, at 8 AM and 4 PM, once maximum follicular diameters reached 16 mm. Seven days after ovulation, as documented by ultrasonography, blood was drawn at 8 AM for progesterone levels.

In the treatment cycles monitoring was carried out in an identical fashion. Once follicle sizes reached 16 to 18 mm, Nal-Glu (50 μ g/kg) was administered intramuscularly each morning at 8 AM. Nal-Glu was obtained from the Salk Institute in a collaborative project with S.S.C. Yen, MD, DSc, University of California, San Diego. The 50 μ g/kg dose was chosen on the basis of previously reported dose-response studies in which a maximal suppression of LH (51% to 63%) occurred in postmenopausal women within 5 to 8 hours; the duration of this effect was 24 hours.¹⁷ Nal-Glu was administered for 3 to 4 consecutive days, the time estimated to prevent normal ovulation on the basis of known patterns of follicle growth.

Hormonal assays. All blood was separated, and sera were stored at -20° C until analyzed. Serum LH, follicle-stimulating hormone (FSH), estradiol, and progesterone were measured by highly specific radioimmunoassays. ^{18, 19} Serum estradiol concentrations were measured by radioimmunoassay (Pantex, Los Angeles) after extraction with hexane/ethyl acetate (2:3). In addition, LH also was measured by time-resolved fluo-

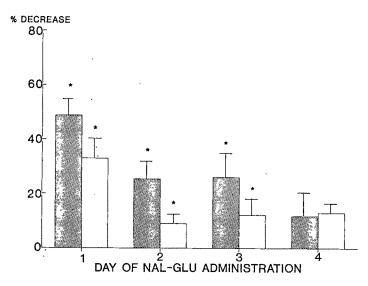

Fig. 2. Mean ± SE percentage decrease of LH (hatched bars) and FSH (dotted bars) between 8 AM and 4 РМ during Nal-Glu (50 μ g/kg intramuscularly) administration at 8 Λ M. Asterisks, Decreases (p < 0.01) in LH and FSH as compared with baseline levels.

roimmunoassays at SmithKline Beecham Clinical Laboratories, Van Nuys, Calif., with Delfia human LH spec kits, according to the method of Lovgren et al.20 All sera from each patient were run in a single assay to decrease variation. The mean intraassay and interassay coefficients of variation for the serum radioimmunoassays were as follows: LH, 2.7% and 10%; FSH, 5% and 10%; estradiol, 8.4% and 13%; and progesterone, 6.2% and 7%, respectively. The intraassay and interassay coefficients of variation for the LH serum fluoroimmunoassays were 5% and 7%, respectively.

Statistical analyses. All data are expressed as the mean ± SEM. Statistical analyses were performed with paired t tests, and regression analyses were carried out with Pearson's regression analysis.

Results

Midcycle data of the eight normal ovulatory women during control cycles, compared with their data in Nal-Glu cycles, are depicted in Fig. 1. With Nal-Glu, gonadotropins were abruptly inhibited, and ovulation did not occur according to ultrasonographic criteria. Nal-Glu also decreased serum estradiol levels and arrested follicle growth. Serum estradiol decreased by 43.1% = 8%, $53.2\% \pm 9\%$, $50\% \pm 15\%$, and 47% ± 13% in comparison with pretreatment baseline values during the 4 days of Nal-Glu administration. The follicular diameters remained essentially unchanged (16.9 \pm 0.4 to 17.25 \pm 1.1 mm). When Nal-Glu was matched to control cycles, the initial day of Nal-Glu administration corresponded to 2.2 days before ovulation.

Serum LH values at 8 AM decreased significantly during Nal-Glu treatment. Mean values were 29 ± 9, 16 ± 2 , 17 ± 2 , and 16 ± 7 mIU/ml during Nal-Glu

treatment. Corresponding values for FSH were 13 ± 3, 7 ± 1 , 8 ± 1 , and 7 ± 1 mIU/ml. The percentage changes in LH and FSH after each dose of Nal-Glu is depicted in Fig. 2. These percentages represent the changes between the 8 AM and 4 PM blood samples. Serum LH levels consistently decreased more than FSH levels except on day 4, when these changes were similar.

We also measured LH by fluoroimmunoassay. LH levels decreased by $71.3\% \pm 6.5\%$, $61.3\% \pm 6.3\%$, $48.8\% \pm 7\%$, and $26.1\% \pm 9\%$. This percentage decrease was significantly greater than the radioimmunoassay measurements on days 2 to 4 (p < 0.05).

In treatment cycles, after the last dose of Nal-Glu, spontaneous follicular rescue occurred in eight of 10 cycles. Fig. 3 illustrates the LH, FSH, and estradiol levels and follicular diameters during the days from the last Nal-Glu injection until the subsequent ovulation. On the average, 4.1 ± 0.6 days (range 1 to 8) was required for the subsequent gonadotropin surge to occur and 5.1 ± 0.6 days (range 3 to 9) for the patients to ovulate, as assessed by ultrasonography. The average follicular diameter of 16.9 ± 0.5 mm on the last day of Nal-Glu increased to a maximum of 19.3 ± 0.7 mm, whereas the average estradiol measurement increased from 128.5 ± 20.7 pg/ml on the last day of Nal-Glu to $337 \pm 20.8 \text{ pg/ml} (p < 0.01).$

Table I summarizes the effect of Nal-Glu at midcycle by using each patient's control cycle as reference. Of the eight patients receiving Nal-Glu, two had repeat cycles, resulting in 10 monitored cycles. The individual patients are listed with their observed normal cycle lengths, their estradiol and follicular diameter values at the beginning of Nal-Glu administration, the cycle days on which Nal-Glu was given, and when ovulation occurred after Nal-Glu administration. Patient 2 un-

derwent a second Nal-Glu injection because a secondary follicle developed although the LH surge was inhibited. This patient probably had luteinization of two follicles in that they persisted and did not continue to grow. The progesterone level was 4.5 ng/ml 4 days later. Patient 3 also had a repeat cycle because she had an LH surge (105 IU/ml) the day she was first seen, before receiving the first dose of Nal-Glu. However, in this cycle ovulation did not occur and there was subsequent recovery. In a subsequent cycle Nal-Glu was administered 1 day earlier, although the follicle size was

only 14 mm. With patient 7 the cycle was interrupted irreversibly and there was no recovery. She bled 2 days after Nal-Glu when the estradiol level had decreased to 67 pg/ml from a value of 277 pg/ml on the first day of Nal-Glu. Subsequently, this patient had a normal cycle, and a new follicle was observed to develop.

We compared the estradiol/follicular diameter ratio in control cycles before ovulation (13.6 \pm 1) and during the last day of Nal-Glu (7.5 \pm 1.2) and immediately before the subsequent ovulation after recovery from Nal-Glu (16.8 \pm 1.1). The mean estradiol/follicular di-

^{*}Double-dominant (luteinized follicles).

[†]Surge before Nal-Glu.

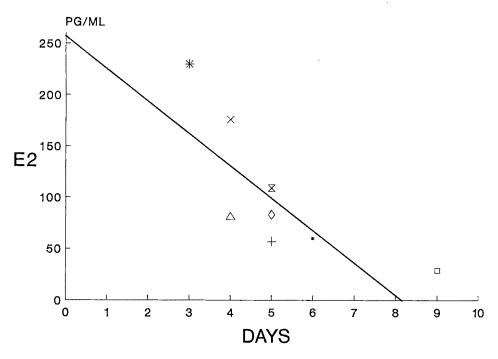

Fig. 4. Correlation between lowest estradiol (E2), level during Nal-Glu administration and time required for subsequent ovulation to occur (r = 0.77, p < 0.05).

ameter ratio in the control group was significantly different from the other two treatment times (p < 0.01and p < 0.02).

A significant negative correlation was found between the lowest estradiol value after Nal-Glu and the number of days required for subsequent ovulation (r = -0.77, p < 0.05 (Fig. 4).

Luteal function after recovery from Nal-Glu was assessed by comparing the length of the subsequent luteal phase and midluteal progesterone levels with control cycles. Luteal length was 14 ± 0.3 days (range 13 to 15) in control cycles and 14.4 ± 1.0 days (range 12 to 19) after documented ovulation in Nal-Glu cycles. Serum progesterone values 7 days after documented ovulation were similar in the two groups and were 15.5 ± 2.3 ng/ml (range 10 to 16) and 18.8 ± 2.1 ng/ml (range 11 to 26), respectively.

Nal-Glu was well tolerated. A slight discomfort for about 20 to 30 minutes was noted after the first injection. No patient had aberrant responses.

Comment

Our data show that Nal-Glu is able to acutely prevent ovulation when administered at midcycle. Although the GnRH antagonist has been used in the follicular phase in previous studies, our data suggest that when it is administered as late as the day of the LH surge (patient 3), ovulation was also inhibited. In addition, evidence was provided that follicular rescue occurs after Nal-Glu with subsequent ovulation occurring in eight of 10 cycles. Recovery after Nal-Glu administration was negatively correlated with the decrement in estradiol with treatment. With subsequent ovulation, apparent normal luteal function was found to occur, although this assessment was based only on a single serum progesterone measurement. Whereas the viability of the oocyte after several days of arrested follicular growth remains uncertain, pregnancies have resulted after in vitro fertilization when Nal-Glu was used.21 During Nal-Glu treatment and subsequent recovery, an estradiol/follicular diameter dissociation was evident, as compared with control cycles.

At midcycle, LH was inhibited by 12% to 49% by radioimmunoassay and 36% to 71% by fluoroimmunoassay. The fluoroimmunoassay measurement is thought to better reflect the biologic activity of LH and is compatible with the known effects of the antagonist on LH.22 The greater inhibition of LH compared with FSH has been noted by other investigators.^{23, 24} These differences could be explained either by differences in half-lives of the gonadotropins or by a differential regulation of secretion.

Correlations were carried out for changes in the gonadotropins, estradiol, and follicular diameters in the control cycles, whereas patients were receiving Nal-Glu and after Nal-Glu during the recovery period. Serum LH always correlated significantly with FSH (p < 0.01). Serum estradiol correlated significantly with follicular diameters (p < 0.01), except during Nal-Glu administration.

Our recovery data suggest that even after sustained gonadotropin deprivation at midcycle, follicular recovery is possible in at least eight of 10 cycles. That the time to recovery was inversely correlated with the suppressed estradiol levels suggests that profound or more prolonged suppression may result in follicle atresia. With recovery, estradiol levels rapidly increased, whereas follicle size did not increase commensurately. This observation suggests that follicle growth and its steroidogenesis may be dissociated and may not be under the same regulatory control.

Although it was determined in monkeys >10 years ago that destruction of the dominant follicle resulted in a subsequent follicle development requiring 10 to 12 days,25,26 a variable recovery of the dominant follicle was noted to occur after another GnRH antagonist was used in monkeys at midcycle.27 Furthermore, Detirelix, another second-generation antagonist, which is less potent than Nal-Glu,17 was reported recently to inhibit follicular development in the late follicular phase, allowing for subsequent recovery and ovulation in four normal women.28 That recovery of a dominant follicle would occur after 3 to 4 days of antagonist administration and 5.4 ± 1.4 days of estradiol decrement was somewhat of a surprise but did occur in 80% (8/10) of our cycles tested. However, it appears obvious that more prolonged suppression of estradiol may lead to irreversible follicular or oocyte atresia.

Nal-Glu appears to be useful in in vitro fertilization for down regulation before gonadotropin stimulation and for preventing premature luteinization and a premature LH surge. Our data would suggest that for preventing a premature LH surge Nal-Glu may be administered extremely late in folliculogenesis and need be administered only just before the LH surge. If it is administered earlier in the follicular phase, supplementation with gonadotropin would be necessary to prevent follicles from becoming atretic.

Reduction of primary posttraumatic adhesion formation with the prostacyclin analog iloprost in a rodent model

Alex Steinleitner, MD,^{a,b} Hovey Lambert, PhD,^a Mariluz Suarez, BS,^b Nurys Serpa, BS,^a and Beverly Robin, BS^b

Miami Beach and Miami, Florida

Recent evidence suggests that inhibition of postsurgical adhesion formation may be effected by modulation of the activities of inflammatory cells contributing to mesothelial repair. Iloprost, a stable analog of prostacyclin, has been shown to exert vasodilatory, antiinflammatory, fibrinolytic, and antithrombotic influences. To determine whether these properties of iloprost might protect mesothelial surfaces from perioperative damage and hence prevent adhesion formation, we evaluated the effect of iloprost on peritoneal healing in a hamster model for primary pelvic injury. Perioperative iloprost therapy significantly reduced posttraumatic adhesion formation when compared with that in vehicle-treated controls. Doseresponse studies demonstrate adhesion prevention with doses ranging from 0.04 to 4 mg/kg per 8 hours given subcutaneously over the course of 3 days. These data demonstrate that iloprost is a potent positive modulator of peritoneal healing after pelvic trauma. Further studies to characterize the potential application of iloprost as an adjuvant in reproductive surgery are indicated. (AM J OBSTET GYNECOL 1991;165:1817-20).

Postsurgical adhesion formation is a nonspecific inflammatory process directed primarily by activated peritoneal macrophages. Contemporary research in the development of adhesion prevention regimens emphasizes the use of immunomodulation of inflammatory cell activity to reduce mesothelial injury and to enhance normal reperitonealization. Iloprost, a stable analog of prostacyclin, has been shown to exert vasodilatory, antiinflammatory, fibrinolytic, and antithrombotic influ-

Table I. Scoring system for postsurgical adhesion formation

Adhesion score	Location	Thickness	Extent
0 1+ 2+	No adhesions Intrauterine horn adhesions Adhesions from the uterine horn to bowel	No adhesions Filmy adhesions Thick adhesions	No adhesions Adhesions covering <50% of injured surface Adhesions covering >50% of injured surface

ences. We hypothesized that these properties might be used to influence posttraumatic mesothelial repair and to reduce the incidence of intraperitoneal adhesion formation. We present the results of preliminary experiments evaluating the effect of iloprost on primary posttraumatic healing in a rodent model.

Methods

The hamster model for primary posttraumatic peritoneal repair used in these experiments was derived from procedures previously developed and validated in our laboratory. Sexually mature female golden hamsters (Harlan-Sprague Dawley, Indianapolis) that were 6 to 8 weeks of age and that weighed 100 to 150 gm) were observed in quarantine for 10 days before use in these experiments. They were fed standard laboratory chow and water as desired and were maintained on a cycle of 14 hours light/10 hours dark.

A standardized adhesiongenic lesion was performed on each animal at laparotomy. Preoperatively each animal received 1.0 mg of penicillin G (Squibb, Princeton, N.J.) subcutaneously 30 minutes before surgery. Anesthesia was induced by intraoperitoneal injection of pentobarbital, 0.5 mg (Abbott Laboratories, North Chicago). Midline laparotomies were performed under clean but not sterile conditions. Care was taken to maintain gross hemostasis during the procedure. At laparotomy the left uterine horn was identified and brought out of the wound. Battery-powered unipolar ophthalmologic cautery was used to create a standardized adhesiongenic lesion consisting of devascularization of the entire vascular arcade of the left uterine horn, placement of 12 to 15 serosal burns along the distal 3 cm of the antimesenteric surface of the horn, and the opening of a 1.5×1.5 cm defect in the mesentery. This lesion had previously been shown to produce adhesions between the uterine horn and the bowel and/or pelvic sidewall in >90% of treated animals. The right uterine horn was not manipulated and served as an internal control. Abdominal closures were performed in two layers with 4-0 polyglycolic acid sutures.

Immediately before surgery, hamsters were randomly assigned to control or experimental treatment groups. Each animal received nine subcutaneous injections of the study medications at 8-hour intervals that began 30 minutes before operation. Experimental treatments included: vehicle (saline solution, n = 10)

and iloprost (Berlex Laboratories, Cedar Knolls, N.J.) in doses of 4, 0.4, 0.04, and 0.004 mg/kg (n = 10 per group). Dosage intervals were based on the amount of iloprost used to modulate cardiovascular function in rodents.²

Two weeks after the initial laparotomy, all animals were killed by cervical dislocation for assessment of adhesion formation. The location, extent, and thickness of induced adhesions were separately graded in a blinded manner by the original surgeons on a scale ranging from 0 to 2+ (Table I), which yielded a maximum cumulative score of 6+. All data are reported as the mean \pm SEM. Nonparametric statistics (Kruskal-Wallis and Mann-Whitney U tests) were used to compare the outcome of postsurgical healing.

Results

The standardized adhesiongenic lesion used in this model, in accordance with our previous experience, consistently induced the formation of dense adhesions between the injured uterine horn and the bowel and pelvic sidewall. The mean adhesion score for control animals was 5.8 ± 0.2 . Nine of 10 hamsters were found to have maximal (6+) adhesive involvement at necropsy. No control hamster scored <4+.

Administration of nine perioperative doses of iloprost produced a dose-dependent reduction in adhesion formation (Table II). Maximal adhesion reduction was seen in hamsters receiving the 4 mg/kg dose. Mean total adhesion score in this group was 0.7 ± 0.5 (different from control, p < 0.001, Kruskal-Wallis test). Eight of 10 animals in this group were completely free of adhesions at necropsy. Significant adhesion reduction also was observed with the doses of 0.4 and 0.04 mg/kg (total score, 1.3 ± 0.5 and 1.9 ± 0.5 , respectively). Reductions in total adhesion scores in these three groups were the result of an equal decrement in the scores for the separate parameters of adhesion location, thickness, and extent. Hamsters treated with a dose of 0.004 mg/kg were found to have extensive adhesion formation (average score, 5.2 ± 0.3), which was not different from controls.

Perioperative treatment with iloprost was not associated with significant postsurgical morbidity. No evidence of increased intraperitoneal infection, failure of wound healing, or obvious bleeding dyscrasias was observed. Hamsters treated with the highest dose of ilo-

prost (4 mg/kg) were noted to display increased agitation when compared with control animals.

Comment

Peritoneal repair after traumatic or infectious injury is essentially a nonspecific inflammatory process, the course of which is dependent on the interaction of numerous immune mediators and inflammatory cells. Studies by Raftery^s and others have divided this process into three stages: an acute postinjury phase, initiation of fibrinolysis and clot resorption 48 hours later, and reperitonealization over the ensuing 14 days. The activated peritoneal macrophage appears to be the principal director of cellular elements that contribute to mesothelial repair.4 Other inflammatory cells, including neutrophils, endothelial cells, platelets, and fibroblasts, may contribute to posttraumatic healing. Under ideal conditions, macrophage-directed reperitonealization produces complete restoration of mesothelial continuity without evidence of scarring or previous trauma. In contrast, excessive tissue injury or exposure to inflammatory stimuli may lead to the formation of dense sheets of adhesions that connect adjacent structures and interfere with normal organ function.

Researchers studying problems in intraperitoneal healing and adhesion prevention have long recognized that the course of peritoneal wound repair may be favorably altered by modifying the activities of inflammatory cells to reduce nonspecific tissue injury. Early investigators viewed this phenomenon largely as an "allor-none" phenomenon. Their goal was to entirely eliminate the phagocytic component of the acute postinjury phase by obliterating the inflammatory response to tissue trauma. Powerful immunosuppressive agents such as corticosteroids were used for this purpose.5 Other important aspects of peritoneal repair were largely ignored. More recent data have shown that immunocompetent cells have an essential role in reperitonealization that extends beyond the acute postinjury phase. It has become increasingly apparent that the goal of contemporary adhesion prevention regimens should be to redirect the activity of inflammatory cells to obtain posttraumatic tissue homeostasis (e.g., prevention of infection, phagocytosis of injured cells) without comprising the essential activity of these cells in the subsequent

phases of fibrinolysis and macrophage-directed reperitonealization. Thus investigators have more carefully examined the pathophysiologic factors of peritoneal repair to elucidate the specific contributions of various inflammatory cells to peritoneal healing and adhesion formation.

Platelet activation, platelet-endothelial cell interaction, and thrombosis are commonly overlooked, but they are essential contributors to each phase of posttraumatic peritoneal repair. Platelet activation after tissue disruption results in the release of a variety of inflammatory mediators and growth factors (platelet-derived growth factor, thromboxane A2, platelet factor 4, transforming growth factor-β, connective tissue activating peptide III, β-thromboglobulin, and epidermal growth factor), which attract and activate inflammatory cells. Platelet activation and release of platelet-derived mediators may adversely affect the sequential aspects of peritoneal healing by increasing nonspecific phagocytic damage and by stimulating fibroblast proliferation and collagen deposition. This process may lead to cellularization of fibrinous adhesions that bind adjacent intraperitoneal structures and to aberrant collagen deposition and the formation of dense cellular intraperitoneal adhesions.

Prostacyclin, a product of the cyclooxygenase pathway of prostaglandin synthesis, is an essential regulator of vascular tone, platelet function, and thrombosis after vascular injury. Review of the prostacyclin literature suggests that this eicosanoid may exert direct and indirect influences on the inflammatory milieu of injured tissue. Vascular elaboration of prostacyclin may reduce nonspecific phagocytic tissue injury by inhibiting the production of inflammatory cell chemotactic and activating factors and by ameliorating inflammatory cell activation (inhibition of neutrophil superoxide6 and leukotriene B4 production,7 inhibition of lymphocyte proliferation,8 and inhibition of macrophage Ia expression9). Fibrinolysis, a critical step in mesothelial healing, is moderately stimulated by prostacyclin.

As a result of knowledge of the effect of prostacyclin on platelet activation, thrombotic homeostasis, inflammatory cell activation, and fibrinolysis, we theorized that prostacyclin analogs might be useful as modulators of posttraumatic peritoneal healing to reduce perioperative adhesion formation. Iloprost, a long-lasting orally active prostacyclin analog, shares many properties of the parent compound. Vasodilatory, platelet-suppressant, fibrinolytic, and "cytoprotective" activities of iloprost equal or exceed those of prostacyclin.10, 11 The results of this preliminary investigation demonstrate that perioperatively administered iloprost is a potent inhibitor of primary pelvic adhesion formation. This activity occurred in a dose-dependent manner; maximal adhesion reduction was observed with a dose of 4 mg/kg. The therapeutic index of iloprost in this indication was fairly broad; significant adhesion prevention occurred over two orders of magnitude. Reduction of total adhesion score was the result of equal contributions from adhesion location, thickness, and extent. Perioperative administration of iloprost did not lead to increased infectious morbidity, failure of wound healing, or obvious bleeding disorders.

These data provide additional support to the emerging concept of the use of "immunomodulatory" (as opposed to "antiinflammatory") agents to enhance postsurgical peritoneal repair. In recent communications we have reported the results of studies in which calcium channel blocking agents, pentoxifylline, and bioactive peptides such as somatostatin and synthetic substance P antagonists (unpublished observations) have been used to prevent posttraumatic adhesion formation in animal models. These agents are not considered to be classic antiinflammatory agents. Rather, these distinctly different classes of agents appear to affect peritoneal repair by modulating the activities of inflammatory cells participating in the adhesion formation cascade. The beneficial influence of the previously mentioned immunomodulatory drugs on adhesion formation appears to result primarily from alterations of macrophage and neutrophil function. Modulation of platelet function with iloprost may provide another means by which to perturb the adhesion formation cascade. Further studies designed to examine the pharmacokinetics and mechanism of iloprost-mediated adhesion prevention and its potential application in the clinical setting are indicated.

The effect of the menstrual cycle and of decompression stress on arachidonic acid—induced platelet aggregation and on intrinsic platelet thromboxane production in women compared with men

Sanford M. Markham, MD, Norman H. Dubin, PhD, and John A. Rock, MD Baltimore, Maryland

Menstrual cycle variations in platelet aggregation and thromboxane production in association with sex steroids have been reported. External stimuli such as decompression sickness have been associated with clotting activity changes, specifically, increased platelet aggregation. Differences in response of platelets from women and men, when subjected to such a stress, have been observed. This study evaluated the ability of washed platelets from women in the proliferative and secretory phases of the menstrual cycle to aggregate in response to arachidonic acid and the aggregation difference between washed platelets from women and men in response to decompression stress and arachidonic acid. Additionally, platelet thromboxane production differences between the assessed platelet populations were compared. Our results indicate no difference in platelet aggregability between phases of the menstrual cycle. A significant aggregation difference between platelets from women and men was noted. Platelets from women were more sensitive to arachidonic acid aggregation. These differences were not affected by decompression stress. No difference in thromboxane B2 production was noted between the platelet populations evaluated. (AM J OBSTET GYNECOL 1991;165:1821-9.)

Key words: Platelet aggregation, sex differences, decompression stress response

The relationship of arachidonic acid and its metabolites to platelet aggregation has been a source of intense interest to the hematologist and the endocrinologist. The physiologic actions of arachidonate metabolites and of platelet activities have been of interest to the obstetrician-gynecologist only recently. In 1985 Ylikorkala and Makila¹ published an extensive report reviewing a number of relationships between arachidonic acid metabolite activity and reproductive tract malfunction. Their article focused on thromboxane and prostacyclin and their effect on menorrhagia, uterine contractility, endometriosis, preeclampsia, and gynecologic cancer. Other studies have focused on changes in platelet aggregation during the menstrual cycle² and in relationship to sex steroids.^{3,4} Additional studies have addressed platelets as a source of sex steroids3 and the role of platelet antiglobulins in the pathogenesis of preeclampsia. These studies leave unanswered the true effect of sex steroids on platelet aggregation and the

possibility that aggregation might vary between sexes. If such a difference were true, then women might be at risk for vascular thrombosis during the menstrual cycle and at greater risk than men in some work environments.

One such work area is the aerospace industry with increasing roles of women as pilots and, more recently, as astronauts. Sex differences in decompression sickness and other altitude pressure—related phenomena have appropriately attracted attention. ⁷⁻⁹ Decompression sickness has been associated with altered clotting activity, specifically, increased platelet aggregation. ¹⁰⁻¹² The possibility that sex differences may exist between platelets from women and men and their ability to aggregate when subjected to chemical and physical stimuli also has prompted considerable interest. ¹³⁻¹⁸ These data also leave unclear whether intrinsic platelet factors or extrinsic blood factors are the cause of observed aggregation differences.

Our studies focus on differences between platelets from women and men to aggregate in response to a stimulus of arachidonic acid in the proliferative and secretory phases of the menstrual cycle and before and after exposure to decompression stress. Additionally, differences in platelet thromboxane B₂ production between platelets from women and men were assessed. Washed platelets were used to eliminate sex variations in plasma components.

Material and methods

Study 1: Platelet aggregation and platelet thromboxane production in proliferative versus secretory phase of menstrual cycle. Twenty-four women were studied, 12 in the proliferative phase and 12 in the secretory phase of the menstrual cycle. The volunteers were free of any acute or chronic disease process. All volunteers denied the use of any medications, specifically, steroids and prostaglandin synthetase inhibitors in the 2-month period before sampling. All volunteers reported regular menstrual cycles of approximately 28day intervals with normal flow. Those volunteers whose cycle were in the proliferative phase had blood taken during cycle days 6 through 12, and those in the secretory phase had blood taken from cycle days 18 through 24 on the basis of the beginning of the last menstrual period. All volunteers were between the ages of 20 and 43 years with a mean age of 29 years. The mean age of volunteers in the proliferative phase was 31 years and in the secretory phase was 27 years. All samples were obtained from a vein in the antecubital area of the arm between 8 and 8:30 AM in the nonfasting state. This study was approved by the Joint Committee on Clinical Investigation of The Johns Hopkins Medical Institutions, Baltimore.

Study 2: Effect of decompression stress on platelet aggregation and platelet thromboxane production in women and men. Six women and six men volunteers were recruited from flight crews on active duty in the United States Air Force at Andrews Air Force Base, Maryland. Ages of volunteers ranged from 28 to 41 years with a mean age for women of 36 years and a mean age for men of 31 years. All subjects were medically qualified for flight operations. No differentiation as to proliferative or secretory phase of the menstrual cycle was made in the women of the volunteer group. All blood samples were taken from a vein in the antecubital area of the arm at 8 AM while the subjects were in a nonfasting state. Immediately after the preflight blood sampling the subjects entered a hypobaric chamber at the Physiological Training Unit at Andrews Air Force Base and a modified type III hypobaric chamber flight was accomplished. The flight lasted for 1 hour, during which time all subjects were breathing 100% oxygen by mask until the final recompression at the end of the flight. The flight consisted of an initial decompression to 5000 feet, before which all subjects completed 30 minutes of oxygen breathing to assure denitrogenation. After this a recompression back to sea level was accomplished to correct any oxygen mask malfunctions or trapped gas problems. The chamber was then decompressed to 35,000 feet to create a decompression stress. After stabilization at 35,000 feet the chamber was recompressed to 25,000 feet, where it was leveled, and each volunteer participated in a hypoxia exercise consisting of removal of the oxygen mask until symptoms of hypoxia were experienced. Oxygen masks were then replaced, and after a short period of stabilization the chamber was further recompressed to 18,000 feet, at which point all volunteers were switched to normal oxygen (20% oxygen) for the remainder of the recompression back to sea level. Immediately after return to sea level each volunteer exited the chamber and a second blood sample was obtained. This study was approved both by the Joint Committee on Clinical Investigation of The Johns Hopkins Medical Institutions and by the Air Force Human Use Committee, Office of the Surgeon General, Bolling Air Force Base, Washington, D.C.

Platelet aggregation. From each volunteer in both studies a 20 ml blood sample was drawn into a plastic syringe with an 18-gauge needle. Nine milliliters of the whole blood sample was placed into each of two plastic centrifuge tubes, to which was added 1 ml of buffered sodium citrate at room temperature. An immediate hematocrit was accomplished on the remaining whole blood sample.

The citrated blood was centrifuged at 21° C at 190g for 15 minutes. After centrifugation, the platelet-rich plasma was drawn off, the amount recorded, and the remaining packed cells were discarded.

The platelet-rich plasma was centrifuged at 21° C at 760g for 15 minutes. The resulting platelet pellet was rinsed twice with a small amount of Tris-buffered saline solution (0.15 mol/L, pH 7.4), with 2.0% disodium ethylenediaminetetraacetate (EDTA). An additional amount (1 to 2 ml) of Tris-buffered saline solution with EDTA was added and the platelet pellet was resuspended by vortex blending. The suspension was diluted by additional Tris-buffered saline solution with EDTA to equal the volume of platelet-poor plasma previously removed.

The resuspended platelets were centrifuged at 21° C at 760g for 15 minutes, after which the supernatant was discarded. The platelet pellet was resuspended with 10% Tris in Hanks' balanced salt solution without calcium to the same volume as before centrifugation. A platelet count was accomplished by making a 1:100 dilution of the washed platelet solution with Tris without calcium. Platelets were counted on an improved Neubauer AO hemocytometer (Buffalo, N.Y.).

The washed platelets from each volunteer were diluted to a mean concentration of 170,000 cells per milliliter and evaluated for aggregation in response to arachidonic acid. All evaluations were accomplished within a 3-hour period from sampling (range, 1 to 3 hours). A 400 μ l sample of washed platelets was placed in each of seven aggregometer cuvettes and preheated

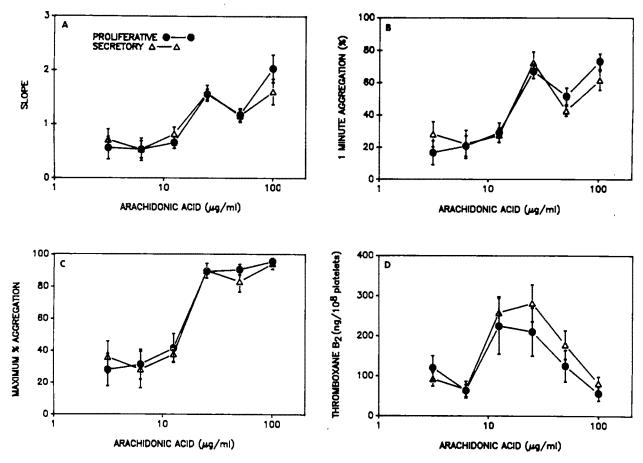

Fig. 1. Aggregation and thromboxane B2 production by isolated platelets from women in proliferative versus secretory stage of cycle.

to 37° C. Then 100 µl of Hanks' balanced salt solution with calcium (1.26 mmol/L) was added to each cuvette and preincubated for 1 minute, after which the arachidonic acid was added in doses ranging from 0 to 100 μg/ml (0, 3.12, 6.25, 12.5, 25, 50, and 100). The aggregation curves produced were then evaluated for slope, aggregation at 1 minute, and maximum aggregation at 5 minutes. After aggregation, all samples were quick frozen at -70° C in a freezer (Revco Scientific, Inc., Asheville, N.C.) and saved for subsequent thromboxane B2 assay.

All frozen samples of washed platelets from study 1 and study 2 were assayed for thromboxane B2 concentration by radioimmunoassay as previously described and validated.19

Data analysis. After completion of the two studies the results were compared between the two groups in study 1 and the two groups in study 2. Data were analyzed by analysis of variance of a nested and repeatedmeasure design.20 For study 1 the repeated measure was dose of arachidonic acid and the nested variable was phase of the menstrual cycle. For study 2 the nested variable was male versus female. In this study there were two repeated-measure variables, namely, arachidonic dose and before versus after decompression stress. The F distribution tests were determined, and data were considered significant at p < 0.05.

Results

Study 1. There was a direct relationship between the concentration of arachidonic acid and all aggregation parameters (Fig. 1, A, B, and C). Thromboxane B₂ production increased with arachidonate doses up to 25 μg/ml. However, at 50 and 100 μg/ml the amount of thromboxane B₂ produced by the platelets was actually less than that produced by those stimulated with 25 μg/ml (Fig. 1, D). In spite of this fact, aggregation occurred at maximal levels at 100 µg/ml. There was no difference in platelet aggregation response to arachidonic acid between females in the proliferative and in the secretory phase of the menstrual cycle (Fig. 1, A, B, and C). Likewise, thromboxane B_2 production by arachidonate-stimulated platelets was not affected by stage of the menstrual cycle (Fig. 1, D).

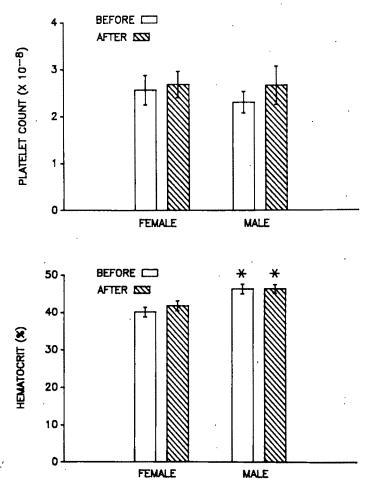

Fig. 2. Platelet count and hematocrit before and after exposure to decompression stress. Males versus females, p < 0.05.

Study 2. In study 2 there was no difference in platelet counts between women and men, but men had a significantly higher hematocrit value (p < 0.05, Fig. 2). Decompression stress did not affect the platelet count or hematocrit.

Platelets from women showed a greater slope in aggregation curve (p < 0.05, Fig. 3) and a greater 1-minute aggregation (p < 0.05, Fig. 4) and maximum aggregation (p < 0.01, Fig. 5) in response to arachidonic acid than did platelets from men. Maximum platelet aggregation was slightly less (6.9%) after decompression stress (p < 0.05, Fig. 5) independent of sex. No other differences in platelet aggregation that were caused by decompression stress were observed (Figs. 3, 4, and 5). Thromboxane B_2 production by isolated platelets was not significantly different between women and men or before or after decompression stress (Fig. 6). However, the same phenomenon of lower thromboxane production in response to the highest concentrations of arachidonic acid was observed.

Comment

The process of platelet aggregation involves a complex cascade of events beginning with platelet membrane receptor exposure and ending with a platelet-platelet bridging by fibrinogen. During this process arachidonic acid from the platelet membrane is converted by the cyclooxygenase pathway to thromboxane A₂. Thromboxane A₂ acts in concert with adenosine diphosphate to recruit circulating platelets and promote aggregation.²¹ The importance of these reactions initially was of interest because of their role in hemostasis. Recently their role in immune and nonimmune defense mechanisms, in embryonic development, and in altered reaction states as a result of sex steroids and external stress has been of increasing concern.

The possibility that platelets might express a sex difference in response to aggregating agents, including sex steroids, and to some forms of stress, such as decompression, has prompted considerable interest to both the basic and clinical researcher, to the aerospace

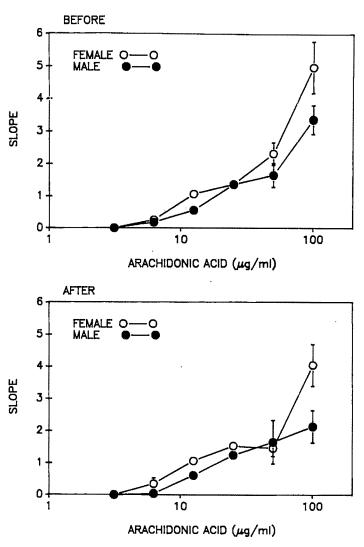

Fig. 3. Slope of platelet aggregation as function of arachidonic acid dose. Males versus females, p < 0.05. Before versus after decompression stress, not significant.

medicine clinician, and to the obstetrician-gynecologist. In the 1960s several articles appeared in support of the idea that platelets from women given estrogen underwent significant behavioral changes, such as increased adhesiveness to a glass surface and increased sensitivity to adenosine diphosphate.22-24 In the 1970s and 1980s, other articles supported the idea that platelets from women showed a greater sensitivity to aggregating stimuli than did platelets from men.13-18 With adenosine diphosphate as an aggregating agent, Johnson et al.13 found that primary aggregation of platelets in young healthy women was significantly increased over values obtained in men, and when epinephrine was used as a stimulant, primary and secondary aggregation also was significantly greater in women than in men. In a later article these investigations17 noted that the sex differences in platelet aggregation in adults most likely were due to an artificially induced difference in plasma calcium levels caused by sex differences in packed cell volume. Roper et al.16 similarly found a difference between aggregation response elicited by adenosine diphosphate for samples from women and men donors and suggested this response was affected to some degree by (1) platelet concentration of the test sample and (2) the time lag from venipuncture to testing. Reading and Rosie¹⁸ have suggested that, though platelets from women have a higher sensitivity than those from men to aggregation by adenosine diphosphate, responsiveness in men increased significantly with age and at a rate greater than that for women, a finding also supported by Johnson et al.13

These data therefore would support an increased sensitivity to aggregation of platelets from women over that in the men; however, the explanation for this dif-

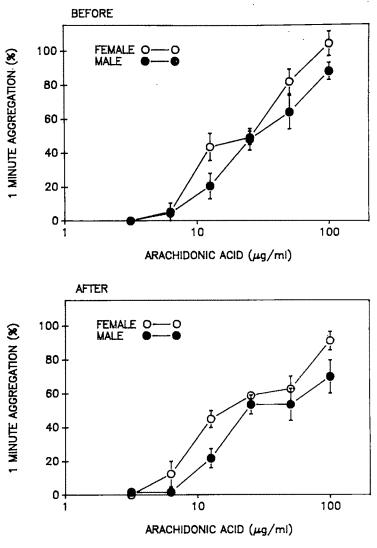

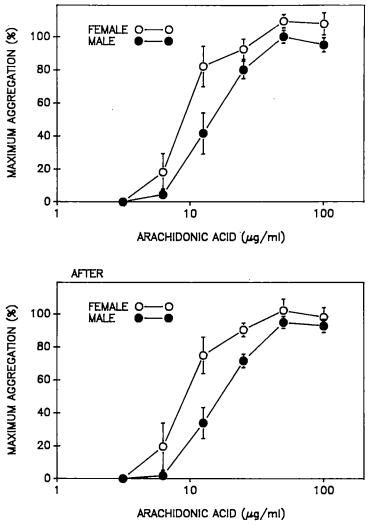

Fig. 4. One-minute aggregation as function of arachidonic acid dose. Males versus females, p < 0.05. Before versus after decompression stress, not significant.

ference is not clear. Only two possibilities for such differences would seem likely: (1) factors intrinsic to the platelet itself (genetic, biochemical) or (2) factors relating to the environment in which the platelets are immersed (plasma factors and/or other blood cells). Most of the reported platelet aggregation studies have been accomplished on whole blood or on platelet-rich plasma; therefore it has been difficult to assess factors of aggregation because of the compounding effect of variations of packed cell volumes, plasma calcium, and other plasma factors on the aggregation process.

In study 1 we have attempted to eliminate some of these variables by using washed platelets to remove plasma and other extrinsic cell factors, focusing on the isolated platelet reaction to a known aggregating agent, arachidonic acid. With this approach our results indicate a direct relationship between concentration of arachidonic acid and all assessed platelet aggregation parameters (slope, 1-minute aggregation, and maximum aggregation), a finding in agreement with the data of others.²⁵ Furthermore, the response was similar in platelets sampled from women during the proliferative and secretory phases of the menstrual cycle. These findings support the idea that sex steroids, or cycle changes in sex steroids, do not directly or acutely alter the ability of isolated platelets to respond to an aggregating stimulus or to produce thromboxane.

Decompression sickness has been associated with increased clotting activity, and there is evidence that increased platelet aggregation leading to intravascular clotting and thrombosis formation may cause some of the symptoms observed in decompression exposure. This idea is supported by the observation that a reduction in platelet count has been noted after decompression in human subjects. Experiments by Jacobs and Stewart, involving severing the tips of tails

BEFORE

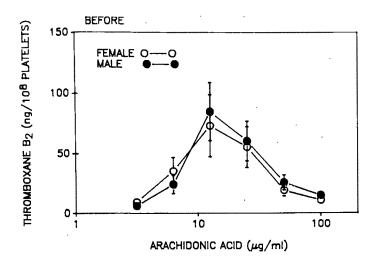

Fig. 5. Maximum aggregation as function of arachidonic acid dose. Males versus females, p < 0.01. Before versus after decompression stress, p < 0.05.

of decompressed rats, revealed a bloody froth issuing from the vessels in the proximal stump of the tail, and on microscopic examination small bubbles surrounded by platelet aggregates were seen. Additionally, experimental decompression in rats has been followed by a loss of circulating platelets and an increase in thrombosis, the extent of which correlated with the severity of decompression symptoms.28

Recently several studies have suggested that decompression stress and decompression sickness occurs more frequently in women than in men.29-31 Bassett29 found that women had a tenfold greater incidence of altitude decompression sickness when compared with that among men. Weien and Baumgartner³⁰ have reviewed 528 cases of decompression sickness resulting from an altitude exposure in either an aircraft or a hypobaric chamber. Their data suggested that the relative risk of decompression sickness necessitating hy-

perbaric therapy was 4.3 times greater for women than for men. An article by Rudge³¹ focused on the relationship of chamber decompression sickness in women related to the menstrual cycle and found a greater incidence at or around the time of menses. These data, as well as a study suggesting an increased potential for decompression stress and decompression sickness in astronauts,32 prompted our study on the effects of decompression stress, produced by a hypobaric chamber flight, on platelet aggregation of washed platelets from women and men.

Our results in study 2, assessing washed platelets from before and after exposure to a decompression stress, showed that platelets from women had a greater slope in aggregation curve, as well as a greater 1-minute and maximum aggregation both before and after the stress exposure. This would suggest a sex difference unrelated to the decompression exposure. Maximum

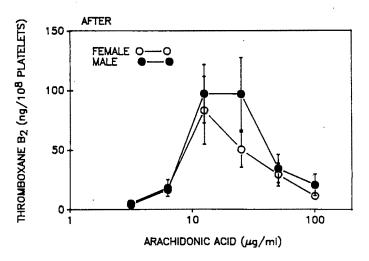

Fig. 6. Thromboxane B2 production by isolated platelets as function of arachidonic acid dose. Males versus females, not significant.

platelet aggregation in women was found to be slightly less after decompression stress (6.9%, p < 0.05). In this study group there was no difference in platelet count or platelet thromboxane production between sexes. Earlier studies²⁵ demonstrated an inhibition in aggregation with arachidonic acid doses >100 µg/ml, and for this reason we did not use larger doses. Surprisingly, we found a smaller amount of thromboxane release from platelets with the highest doses of arachidonic acid used (50 and 100 µg/ml). In spite of the lower amount of thromboxane produced, maximum aggregations still occurred. Thus, at these doses, factors other than thromboxane are responsible for the aggregation. These factors might be other arachidonate products or direct effects of arachidonic acid. Direct effects of nonmetabolized arachidonate have been demonstrated on calcium release by macrophages.33

· Our data with isolated washed platelets indicate that

there is an increased sensitivity of platelets from women compared with men to aggregation as exhibited in each of the aggregation parameters. This difference was observed both before and after an exposure to decompression stress; therefore it is unlikely that decompression itself initiates a gender difference. It is also unlikely that thromboxane production by the platelet plays a role in the gender difference since the production rates between platelets from women and men were statistically similar.

In conclusion, platelet aggregation and thromboxane production appear to have physiologic relationships to many aspects of reproductive medicine. The possibility that platelets aggregate differently during the menstrual cycle or that the thromboxane production is altered in relationship to changes in sex steroids is not supported by our studies. Additionally, our studies support a sex difference in aggregation that is not altered by external factors such as decompression sickness. This is of importance to the obstetrician-gyne-cologist who is assigned the medical care of the increasing numbers of women competing in the aerospace industry.

Tryptophan and neutral amino acids in premenstrual syndrome

Andrea J. Rapkin, MD, Anthony E. Reading, PhD, Stephanie Woo, BA, and Linda M. Goldman, RNP, MN

Los Angeles, California

An abnormality of the serotonin system may play a role in the genesis of the symptoms of premenstrual syndrome, especially those related to mood and appetite. Whole blood and platelet uptake of serotonin are decreased during the luteal phase in women with premenstrual syndrome. The ratio of L-tryptophan (the amino acid precursor of serotonin) to the sum of the other neutral amino acids that compete for the same protein carrier cerebral uptake mechanism has been suggested to reflect central L-tryptophan levels and resultant serotonin levels in the brain. We evaluated the ratio of plasma L-tryptophan to the sum of five competing neutral amino acids in women with premenstrual syndrome and in controls. There were no significant differences between groups or across time, suggesting that it is unlikely that the aberrations of the serotonergic system in women with premenstrual syndrome are due to saturation of the tryptophan-carrying protein. (AM J OBSTET GYNECOL 1991;165:1830-3.)

Key words: Neutral amino acids, premenstrual syndrome

Premenstrual syndrome (PMS) is a psychoneuroendocrine disorder of uncertain cause. Prominent symptoms include the cyclic appearance of marked depression, mood swings, irritability, anger, decreased energy, fatigue, and hyperphagia, specifically cravings for carbohydrate-rich foods; these symptoms may be of sufficient severity to resemble those of affective disorder. However, the presence of a postmenstrual symptomfree week and failure to document biologic markers for depression in well-screened females with PMS suggest that PMS and major affective disorder are discrete entities.¹⁻⁵

There are numerous studies suggesting a disorder of serotonin (5-hydroxytryptamine) metabolism in depression.4.5 Similarly, in subjects with PMS the concentration of 5-hydroxytryptamine in whole blood and the platelet uptake of 5-hydroxytryptamine are diminished during the luteal phase.⁶⁻⁸ The exact mechanism by which a deficiency of the serotonin system may play a role in the genesis of the symptoms of PMS is not yet known. L-Tryptophan, the amino acid precursor of 5hydroxytryptamine, and other large neutral amino acids (e.g., tyrosine, valine, leucine, isoleucine, and phenylalanine) compete for the same saturable carrier protein for transport across the blood-brain barrier. 9 It has been proposed that the ratio of plasma L-tryptophan to the sum of those competing amino acids reflects central L-tryptophan levels and resultant 5-hydroxytryp-

From the Department of Obstetrics and Gynecology, University of California at Los Angeles.

Presented at the Thirty-eighth Annual Meeting of the Society for Gynecologic Investigation, San Antonio, Texas, March 20-23, 1991. Reprint requests: Andrea J. Rapkin, MD, UCLA Medical Center, Department of Obstetrics and Gynecology, CHS Building Room 22-160, 10833 Le Conte Ave., Los Angeles, CA 90024-1740. 6/6/33235

tamine levels in the brain. 9-11 We therefore elected to evaluate the ratio of plasma L-tryptophan to the sum of the five competing amino acids during the follicular and luteal phase in well-screened subjects with PMS and in controls.

Material and methods

Selection of subjects. Subjects with PMS and controls were recruited through newspaper advertisements. Eligibility criteria for subjects with PMS have been previously described in detail¹²; they were required to fulfill the *Diagnostic and Statistical Manual*, third edition, revised,¹³ criteria for late luteal phase dysphoric disorder. Prospective subjects completed a baseline daily symptom diary for 2 months before and during the study. The PMS diary consisted of 11 symptoms, outlined in Table I. All subjects had regular menses with a biphasic basal body temperature curve.

After noneligible subjects were excluded, 18 PMS subjects and 16 control subjects remained for evaluation. Subjects were instructed to abstain from nutritional or hormonal supplements, vigorous exercise, or unusual diets for at least 1 month before phlebotomy. The mean age was 32.4 years and 27.2 years for PMS and control subjects, respectively. Informed consent was obtained in all cases, and the study was approved by the Human Subjects Protection Committee at the University of California at Los Angeles.

Assays. During the third month of the study subjects had venipuncture at 8 AM, after a 12-hour fast. Phlebotomy was performed once on days 8 to 10 of the cycle (day 1 was considered the first day of bleeding) and once on days 24 to 26 of the cycle (10 to 12 days after the midcycle elevation of the basal body temperature curve). Blood was obtained for determination of

Table I. Scores (mean \pm SE) on daily diary for PMS and control subjects during follicular and luteal phase sampling intervals

	PMS subjec	ts (N = 18)	Control subjects $(N = 16)$		
Diary variable	Follicular (mean ± SE)	Luteal (mean ± SE)	Follicular (mean ± SE)	Luteal (mean ± SE)

^{*}Denotes significant differences between PMS and control subjects during luteal phase assessment (p < 0.001).

plasma tryptophan, tyrosine, valine, isoleucine, leucine, and phenylalanine. The assays were performed by Aatron Medical Services (Santa Monica, Calif.).

The deproteinization procedure involved the addition of 400 µg 0.5% sodium dodecyl sulfate to 400 mm³ plasma. The mixture was incubated at room temperature (25° C) for 15 minutes, and the tube was mixed every 3 to 5 minutes. Aliquots of 500 µl of 10% sulfosalicylic acid was then added and gently mixed by hand until homogeneous. Then 700 µl of 0.5 mol/L lithium hydroxide was added, and the mixture was centrifuged for 20 minutes at 2500 rpm at 5° to 10° C. A 400 µl aliquot of supernatant was transferred into a plastic tube to which 400 µl of 2.5 mmol/L s-2-aminomethyl-L-cystine was added. The mixture was then centrifuged for 15 minutes and loaded into a sample loop for injection into the ion-exchange highperformance liquid chromatography amino acid analyzer (model 6300, Beckman Instruments, Inc., Fullerton, Calif.). Ion-exchange high-performance liquid chromatography was used for separation and ninhydrin reaction allowed for visible colorimetry for detection of the above-noted amino acids. The intraassay and interassay variations for amino acid concentrations were <2%.

Statistical analysis. The sum of the five competing amino acids (tyrosine, valine, isoleucine, leucine, and phenylalanine) was determined, and a ratio was computed between L-tryptophan and the five competing amino acids. The ratio was determined for the follicular and luteal phase sampling intervals in the PMS and control subjects. Plasma L-tryptophan to competing amino acid ratios were computed for each menstrual cycle phase as noted above, and comparisons were made between groups and across time on these variables with analysis of variance.

Daily diary scores were calculated by obtaining the

Table II. Tryptophan-to-competing amino acid ratios (mean ± SE) during follicular and luteal phases for PMS and control subjects

	Follicular phase ratio	Luteal phase ratio
PMS $(N = 18)$	0.070 ± 0.013	0.074 ± 0.008
Control $(N = 16)$	0.108 ± 0.023	0.071 ± 0.014

mean and standard deviations for each diary symptom for the day before, the day of, and the day after each venipuncture. The mean scores for each of the symptoms during the follicular and luteal assessment phases of the cycle were then calculated for the PMS and control groups, respectively. Within-group, across-group, and between-group comparisons in the symptom scores were performed with the Student t test and analysis of variance, where appropriate, to test the differences between the means and for a group-by-phase interaction.

Results

The mean scores on the daily diary are shown in Table I. Subjects with PMS and controls have similar scores during the follicular phase with only the PMS subjects showing significant premenstrual exacerbation of symptoms. There were no significant differences in height or weight between PMS and control subjects.

The mean L-tryptophan—to—competing amino acid ratios during the follicular and luteal phase for PMS and control subjects were outlined in Table II. There were no significant differences between groups or across time in the L-tryptophan—to—competing amino acid ratios.

Comment

Decreased serotonergic activity and decreased platelet uptake of 5-hydroxytryptamine have been reported

[†]Denotes significant differences between PMS and control subjects during follicular phase assessment (p < 0.05).

in patients with endogenous depression.^{4, 5, 14} Similar findings have been noted in the luteal phase in women with PMS.⁶⁻⁸ The importance of the serotonergic system in regulating mood and behavior is further supported by studies in which nonhuman primates that were administered pharmacologic agents that depleted 5-hydroxytryptamine and human subjects who were restricted to tryptophan-deficient diets manifested anger, aggression, social withdrawal, and increased food intake, which resemble the affective and appetitive derangements of PMS.¹⁵⁻¹⁷ Furthermore, treatment with the serotonergic agonist fenfluramine has been reporteed to alleviate PMS symptoms.¹⁸

The principal objective of the present study was to test the hypothesis that diminution of central nervous system L-tryptophan uptake in women with PMS could account for the symptoms seen in the luteal phase in these patients. We tested the hypothesis by estimating, in well-selected subjects with PMS and in control subjects, the ratio of plasma L-tryptophan to the sum of the other large neutral amino acids that compete for the same carrier protein for transport into the central nervous system.

The serotonin levels in the central nervous system are dependent on local conversion of L-tryptophan to 5-hydroxytryptamine, as the latter does not cross the blood-brain barrier. Carbohydrate-rich diets have been shown to increase, and protein-rich diets to decrease, brain L-tryptophan levels in the rat. L-Tryptophan loading has been shown to increase brain tryptophan in dogs and to augment the amino acid metabolite of serotonin, 5-hydroxyindole acetic acid, in the cerebrospinal fluid of both dogs and human subjects. An interesting feature of PMS is the craving for high-carbohydrate diets at the time of maximal symptoms in the luteal phase.

The limiting factor controlling central nervous system uptake of L-tryptophan is the transport protein that carries L-tryptophan and other large neutral amino acids across the blood-brain barrier. Binding to this carrier is competitive and saturable, and therefore central nervous system uptake of L-tryptophan depends not only on peripheral L-tryptophan concentration but also on the levels of the other competing amino acids. Various studies have suggested that the ratio of plasma L-tryptophan to the sum of these competing amino acids predicts central L-tryptophan and resultant serotonin levels in the brain. This ratio also has been found to be decreased in patients with major depressive disorders and depression associated with alcoholism. 23-25

In this investigation we have found that well-selected patients with PMS showed no difference in the luteal phase L-tryptophan-to-competing amino acid ratios when compared with follicular phase ratios or ratios measured in control subjects during the luteal phase. These findings suggest that there is adequate availability of L-tryptophan to the central nervous system in patients with PMS and that if a deficiency in the serotonergic system exists in the luteal phase of patients with PMS it is unlikely to be related to inadequate substrate. It is possible that excess consumption of simple carbohydrates by subjects with PMS in the late luteal phase could have elevated the tryptophan-to-competing amino acid ratios obtained in PMS subjects and thus compensated for an alteration in the ratio that otherwise may have been present. The use of the 12hour fasting sample, however, should have minimized this potential problem.9

This is the first investigation of the L-tryptophan—to—competing amino acid ratio in subjects with PMS. Unlike the results obtained in PMS patients, this ratio has been noted to be decreased in individuals with affective disorders. ^{25–25} This difference between these two clinical conditions again highlights earlier reports that PMS is not a subset of cycling affective disorder. Further studies are needed to identify the differences, if any, in the conversion of L-tryptophan to 5-hydroxy-tryptamine in the central nervous system of these patients, because substrate availability does not seem to be an important factor.

The role of prostaglandins in detrusor instability

Arieh Bergman, MD, Frank Z. Stanczyk, PhD, and Rogerio A. Lobo, MD

Los Angeles, California

To study the role of prostaglandin production by detrusor muscle in women with idiopathic primary detrusor instability, biopsies of detrusor muscle were obtained from 20 women. Nine women had detrusor instability, and 11 women had stable bladders. Prostaglandin $F_{2\alpha}$ and the stable metabolites of prostacyclin and thromboxane A_2 , namely, 6-keto-prostaglandin $F_{1\alpha}$ and thromboxane B_2 , respectively, were measured after in vitro incubations of detrusor muscle for 3 hours. A significant reduction in the production of 6-keto-prostaglandin_{1\alpha} in women with detrusor instability was noted. There were no differences in the production of prostaglandin $F_{2\alpha}$ and thromboxane B_2 , between women with stable and unstable bladders. These results suggest for the first time that women with idiopathic primary detrusor instability may have a deficient production of prostacyclin. (AM J OBSTET GYNECOL 1991;165:1833-6.)

Key words: Prostaglandins, detrusor instability, bladder prostacyclin

From the Department of Obstetrics and Gynecology, University of Southern California School of Medicine, Women's Hospital.

Presented in part at the Thirty-eighth Annual Meeting of the Society for Gynecologic Investigation, San Antonio, Texas, March 20-23, 1991.

6/6/33232

Primary instability of the detrusor muscle is a condition of unknown cause. In some cases the condition is secondary to central nervous system pathology and is called detrusor dyssenergia.^{1, 2} In most cases it is an idiopathic condition for which treatment has not been satisfactory.^{3, 4}

Prostaglandins are known to play a major role in

smooth muscle contraction and to exert an effect on the detrusor muscle as well. In vitro studies have shown that both prostaglandin F2a (PGF2a) and prostaglandin E2 (PGE2) significantly enhance detrusor contractions.5 In vivo studies have shown that prostaglandins, administered either directly to the bladder or systemically, cause effective detrusor contractions and improve bladder function after gynecologic surgery.6,7 Antiprostaglandins have been used in women with uncontrolled bladder contractions and detrusor instability.8 The use of indomethacin for treatment of idiopathic detrusor instability has not gained popularity because of suboptimal efficacy and the significant side effects encountered.8

Therefore our current work was undertaken to assess prostaglandin production by detrusor muscle in women with idiopathic primary detrusor instability. More specifically, we wished to determine the production of prostacyclin, a relaxing, vasodilatory prostaglandin.

Material and methods

Twenty women scheduled to undergo abdominal hysterectomy because of uterine leiomyomas, with or without bladder neck suspension, agreed to participate in this study. The mean age of these women was 51 (range 31 to 76) and mean parity was 3 (range 1 to 9). Eleven of these women were premenopausal and nine were postmenopausal. All postmenopausal women who were not on a regimen of estrogen replacement therapy received such therapy in the form of conjugated estrogens (Premarin, Ayerst Laboratories, New York), 0.625 mg/day for 2 weeks before evaluation and continued this treatment until operation. All women underwent surgery within 4 weeks of evaluation. At surgery, no woman had inflammatory conditions such as salpingitis, pelvic abscess, or endometriosis. All premenopausal women were scheduled to undergo operation at midcycle, although the exact day could not always be determined.

All women underwent preoperative urethrocystometry with a Disa 2100 multichannel electrophysiologic recorder (Dantek Lab, Hoboken, N.J.) and microtip pressure transducer (Millar 60 K 22 microtip catheter, Millar Instrument Co., Houston) for concomitant detrusor and urethral pressure recordings). All tests were carried out with the patients in the standing position with rapid water filling (at a rate of 60 ml/min). Nine of the women in this series had detrusor instability, and 11 women had stable bladders. All with detrusor instability had motor detrusor instability as defined by the International Continence Society.9 The nine with detrusor instability had repeated uninhibited bladder contractions, of >15 cm of water above baseline, starting at bladder volumes of 120 to 275 ml. The 11 women with a stable bladder (International Continence Society definition9) in this series had no detectable bladder contractions on rapid bladder filling in the standing position and had a baseline bladder pressure increase from the beginning of urodynamic testing to maximal cystometric capacity of <15 cm of water. The maximal cystometric capacity of the 11 women with stable detrusor ranged from 320 to 585 ml. Both groups (stable and unstable) were comparable with respect to mean age, parity, and menopausal status. There was no correlation between age and findings of detrusor instability. Mean age of the nine women with detrusor instability was 52 years and that of the 11 women with stable bladder was 50.5 years.

At the time of operation, two punch biopsy specimens were taken from the dome of the bladder. These samples $(1 \times 1 \text{ cm})$ were obtained deep in the detrusor muscle but excluded the bladder mucosa. The biopsy site was then closed with assured 2-0 Vicryl (Ethicon, Summerville, N.J.) sutures, and the integrity of the bladder was assumed by instillation of methylene blue. All specimens were examined histologically for the presence of detrusor muscle fibers.

Bladder incubation procedure. After surgical removal, each specimen of bladder tissue was immediately placed in cold Dulbecco's minimal essential medium (Gibco Laboratories, Santa Clara, Calif.) and incubated within 20 minutes after its removal. The

muscle tissue was first dissected free of serosa and minced finely with a scalpel, weighed rapidly, and placed in a vial containing 2 ml Dulbecco's minimal essential medium. This mixture was then placed in a Dubnoff incubator in an atmosphere of 95% oxygen and 5% carbon dioxide at 37° C for 3 hours. A 0.5 ml aliquot of the medium was taken after 0.5, 1, 2, and 3 hours of incubation to measure prostaglandin levels. Each time an aliquot of the incubated medium was removed, it was replaced with 0.5 ml of fresh Dulbecco's minimal essential medium, to maintain a total incubation volume of 2 ml. The aliquots were stored at -20° C until processed within 1 month following the incubation.

Measurement of prostaglandin levels. Levels of $PGF_{2\alpha}$, 6-keto-prostaglandin $F_{1\alpha}$ (6-keto-PGF_{1\alpha}), and thromboxane B2 (TxB2) were measured by specific radioimmunoassays (RIA). PGF_{2α} was measured with a [3H] PGF2a RIA kit (Advanced Magnetics, Inc., Cambridge, Mass.) with a modified procedure. The modifications included (1) the use of a 0.05 ml aliquot of sample for assay, (2) addition of approximately 2000 dpm to each sample as internal standard to follow procedural losses; and (3) reconstitution of the extract in 1 ml of the assay buffer and use of 0.05 ml of the solution in duplicate for RIA and 0.5 ml to determine the procedural losses.

6-Keto-PGF_{1α} and TxB₂ were quantitated by RIA, after their extraction from separate 0.1 ml aliquots of samples. Before extraction, each sample was diluted with 0.4 ml of assay buffer (phosphate-gelatin buffer consisting of 0.1 mol/L sodium phosphate, pH 7.0, and 0.15 mol/L sodium chloride and containing 0.1% (wt/vol) of Knox unflavored gelatin and sodium azide). To this mixture were added approximately 2000 dpm of the appropriate tritiated prostaglandin (either ³H-6-keto-PGF_{1α} [Amersham Corporation, Arlington Heights, Ill.; specific activity 157 Ci/mmol] or 3H-TxB2 [DuPont NEN Research Products, Boston; specific activity 180 Ci/mmol]) in 0.1 ml of assay buffer. After the mixture was blended in a vortex, its pH was adjusted to 3 to 3.5 with formic acid. The prostaglandins were then extracted with pretreated Bond Elut C18 columns (3 ml; Analytichem International, Harbor City,

Calif.) by sequential elution with 2 ml water, 2 ml benzene, and 3 ml ethyl acetate. The latter solvent, which contained the prostaglandins, was evaporated to dryness under nitrogen at 37° C, and the residue was redissolved in 1 ml of methanol/assay buffer [1:20 vol/vol]. From this solution a 0.5 ml aliquot was taken to determine procedural losses and aliquots of 0.02, 0.05, and 0.1 ml were used for RIA. The 6keto-PGF_{1a} RIA uses ³H-6-keto-PGF_{1a}, in conjunction with anti-6-keto-PGF₁₀, serum (a gift from Dr. Carlo Patrono, Universita Cattolica del Sacro Cuore, Rome), whereas the TxB2 RIA uses 3H-TxB2 in conjunction with anti-TxB₂ serum (The Upjohn Co., Kalamazoo, Mich.). After a 16- to 18-hour incubation at 4° C the free and antibody-bound prostaglandins were separated by adding 0.6 ml of a dextran-coated charcoal (Norit A, Sigma Chemical Co., St. Louis) suspension (0.5% wt/vol charcoal and 0.05% wt/vol dextran).

Data analysis. Data are reported as mean ± SD and are expressed in nanograms per milligram of wet weight of tissue. The two-tailed t test was used for statistical analysis of the data.

Results

Nine of the women in this series had primary idiopathic detrusor instability and 11 women had stable bladders, as assessed by preoperative urodynamics. This information was not made available to the laboratory at the time of incubation or prostaglandin analysis.

There was a progressive increase in the production of $PGF_{2\alpha}$ by both stable and unstable groups during the 3 hours of incubation (Table I). At the end of 3 hours, the $PGF_{2\alpha}$ production was 3.5- and 2.5-fold greater compared with the first hour in the stable and unstable groups, respectively. However, there was no significant difference between the two groups in the production of PGF_{2α} at either 1, 2, or 3 hours after incubation. Essentially no change in TxB2 production by either the stable or unstable detrusor group was observed between the first and third hours of incubation. At the end of the first hour of incubation, the TxB2 production was almost twofold higher in the unstable detrusor group compared with the stable one. However, after the second and third hours of incubation, no significant differences were observed between the two groups.

A slight decrease was observed in 6-keto-PGF_{1α} production by both the unstable and stable groups during the 3-hour incubation period. The production of 6-keto-PGF_{1α}, however, was fivefold to sixfold greater in the incubates of patients in the stable detrusor group as compared with those from patients with detrusor instability. These differences were significant (p < 0.05) (Table I).

No correlations were evident between any of the prostaglandin measurements and either age or menopausal status.

Comment

The results of this study indicate that women with detrusor instability had a significant reduction in the production of 6-keto-PGF $_{1\alpha}$ and an insignificant change in the production of PGF $_{2\alpha}$ and TxB $_2$ by detrusor muscle.

Detrusor instability may at times be secondary to urethral abnormality, which leads to increased sensory input from the urethra, resulting in bladder contractions.10 In women with primary detrusor instability in which the bladder contraction is not preceded by any urethral pressure changes, the best strategy for treatment is to stabilize the bladder by preventing excessive contractions.10, 11 Various medical treatment methods, such as anticholinergics with or without calcium channel blockers, have been advocated,12 in spite of the fact that these treatments do not achieve a high cure rate. In the past other investigators have suggested the use of antiprostaglandins such as indomethacin on the premise that prostaglandins such as PGF_{2α} stimulate smooth muscle contractions.8 This treatment proved to be somewhat beneficial for a minority of patients, but in these women it was often discontinued because of side effects and less than optimal efficacy.8

These and other treatments have not been successful in part because of the empiric nature of the therapy and because the primary cause of detrusor instability is unknown. Prostaglandins are known to stimulate smooth muscle contraction at multiple sites in the body, including the detrusor muscle. Because only the stimulatory effects of PGF_{2a} and TxA₂ on the detrusor have been considered as causes of detrusor instability, we hypothesized that a dysregulation in the production of prostacyclin also could be responsible. In this setting the relaxing effect of prostacyclin on smooth muscle fibers may be aberrant.

Women with detrusor instability in this study had significantly decreased production of 6-keto-PGF_{1 α}, whereas both PGF_{2 α} and TxB₂ levels were normal. Therefore suppressing all prostaglandins in women with detrusor instability would be expected to inhibit

both the relaxing and contractile prostaglandins and the relaxing effects of prostaglandins to a minimum level. These preliminary data suggest that in women with idiopathic primary detrusor instability decreased prostacyclin production results in an abnormality in the balance between contractile and relaxing influences. This in turn may be a primary defect or a secondary effect of an intrinsic abnormality of the bladder. The findings of a decreased prostacyclin/TxA2 ratio in women with detrusor instability may further suggest an abnormality in bladder vascular tone. This decreased detrusor blood flow or perfusion also may be implicated in this pathophysiologic condition. Therefore it may be reasonable to consider treating patients by enhancing the production of prostaglandin rather than by using nonspecific antiprostaglandin agents. Whether this strategy will result in successful treatment of women with primary detrusor instability remains to be established.

We gratefully acknowledge the excellent technical assistance of Ariel G. Vijod and the generous gift of prostaglandin standards from The Upjohn Company, Kalamazoo, Mich.

Is 11β-hydroxyandrostenedione a better marker of adrenal androgen excess than dehydroepiandrosterone sulfate?

Frank Z. Stanczyk, PhD,^a Lilly Chang, MD,^a Enrico Carmina, MD,^b Zdnek Putz, CSc,^c and Rogerio A. Lobo, MD^a

Los Angeles, California, Palermo, Italy, and Lubochna, Czechoslovakia

To determine whether the adrenal androgen 11β-hydroxyandrostenedione is a more sensitive and specific marker than dehydroepiandrosterone sulfate, we compared these serum androgens in 81 women with anovulatory hyperandrogenism before treatment, after corticotropin and corticotropin-releasing-factor stimulation, and after short- and long-term dexamethasone suppression. Of all subjects, 65% and 57% had elevated levels of 11β-hydroxyandrostenedione (>2.0 ng/ml) and dehydroepiandrosterone suifate (>2.8 μg/ml), respectively. However, 11β-hydroxyandrostenedione and dehydroepiandrosterone sulfate levels did not correlate in either the women with hyperandrogenism (r = 0.12) or the 26 normal women (r = 0.29). After 0.25 mg corticotropin was administered intravenously (n = 16), 11β-hydroxyandrostenedione increased by 157% ± 53% (mean ± SEM), whereas dehydroepiandrosterone sulfate, androstenedione, dehydroepiandrosterone, and cortisol increased by $6\% \pm 2\%$, $46\% \pm 10\%$, $416\% \pm 80\%$, and $2326\% \pm 371\%$, respectively. After intravenous administration of 100 µg corticotropin-releasing factor to eight patients, the percent change from baseline level to peak was 148% \pm 26%, 24% \pm 5%, 61% \pm 15%, 117% \pm 15%, and 116% \pm 18% for 11β-hydroxyandrostenedione, dehydroepiandrosterone sulfate, androstenedione, dehydroepiandrosterone, and cortisol, respectively. After 2 mg dexamethasone for 3 days (n = 10), 11β -hydroxyandrostenedione, dehydroepiandrosterone sulfate, androstenedione, and testosterone were suppressed by 95% ± 2%, $74\% \pm 3\%$, $51\% \pm 9\%$, and $32\% \pm 9\%$, respectively. Suppression with 0.5 mg dexamethasone for 3 months lowered 11β-hydroxyandrostenedione and dehydroepiandrosterone sulfate levels equally by 50% ± 14% and 62% ± 12%, respectively. 11β-Hydroxyandrostenedione is a useful marker of adrenal androgen secretion with a calculated sensitivity and specificity greater than that of dehydroepiandrosterone sulfate. The greater sensitivity of 11β-hydroxyandrostenedione over dehydroepiandrosterone sulfate to adrenal stimulation and suppression suggests its unique diagnostic use. (AM J OBSTET GYNECOL 1991;165:1837-42.)

Key words: 11β-Hydroxyandrostenedione, dehydroepiandrosterone sulfate, adrenal androgens, hyperandrogenism

It is often unclear whether the source of increased androgen production in women with hyperandrogenism is the ovary, the adrenal gland, or increased peripheral conversion of androgen precursors. In particular the role of the adrenal glands in the development of hyperandrogenism remains to be established.

Although dehydroepiandrosterone sulfate (DHEAS) has been used as a marker of adrenal androgen production for some time, the concept that DHEAS exclusively reflects adrenal androgen activity has been chal-

From the Division of Reproductive Endocrinology and Infertility, Department of Obstetrics and Gynecology, University of Southern California School of Medicine⁸; the Cattedra di Endocrinologica, Universita di Palermo⁶; and the Institute of Endocrinology, Lubochna.⁶

Presented in part at the Thirty-eighth Annual Meeting of the Society for Gynecologic Investigation, March 20-23, 1991, San Antonio, Teras

6/6/33018

lenged because a significant source of DHEAS may be derived from the ovary by direct glandular secretion, hepatic sulfurylation of DHEA originating from the ovary, or both. Using selective catheterization techniques, Moltz et al.1 found significant peripheral-ovarian gradients for DHEAS in two of eight healthy women with ovulatory cycles. Vaitukaitis et al.2 showed that peripheral DHEAS levels in normal men and women increased progressively with long-term administration of exogenous corticotropin, but failed to respond to shortterm corticotropin stimulation. In contrast, peripheral DHEA levels exhibited a 20- to 100-fold rise when corticotropin was administered on a short-term basis. The discrepancy in the response of DHEAS to short- and long-term administration of corticotropin could be explained if DHEA were peripherally converted to DHEAS.

There is evidence that 11β-hydroxyandrostenedione (11β-A) may serve as a valuable marker of adrenal androgen production in women with hyperandrogen-

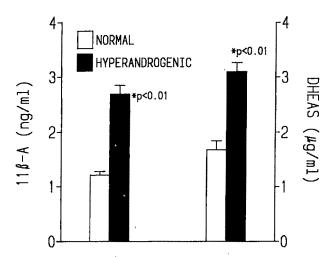

Fig. 1. Serum levels (mean \pm SEM) of 11 β -A and DHEAS in normal women (n=26) and women with hyperandrogenism (n=81).

ism.^{5, 4} 11 β -A is the third most abundant steroid secreted by the adrenal gland and is present in nanogram amounts in blood. However, comparative studies evaluating 11 β -A and DHEAS as biochemical markers of adrenal androgen excess in women with hyperandrogenism have not been reported.

The objectives of this study were (1) to determine whether 11β -A is a more sensitive and specific marker of adrenal androgen excess than DHEAS and (2) to compare the responses of these markers with adrenal stimulation and suppression in women with hyperandrogenism.

Material and methods

Subjects. Study subjects consisted of 26 normal women and 81 women with hyperandrogenism. The women with hyperandrogenism were a mixed group of patients who were initially seen with complaints of androgen excess and who had elevations in serum levels of androstenedione, testosterone, or both. Ages of the normal women ranged from 18 to 30 years; the ages of the women with hyperandrogenism were 18 to 28 years. The body weights of the normal women and the women with hyperandrogenism were $112\% \pm 5\%$ and $117\% \pm 24\%$ (mean \pm SD), respectively, of the ideal body weight.

Treatment and sampling. Sixteen women with hyperandrogenism were treated intravenously with 0.25 mg α^{1-24} -corticotropin (cosyntropin). Blood samples were collected before treatment and 30-minutes after treatment.

Eight women with hyperandrogenism were treated intravenously with 100 μg of ovine corticotropin-releasing factor (Cambridge Research Biomedicals, Ltd., Cambridgeshire, England). Blood sampling was carried out at 0, 30, 60, 90, and 120 minutes after treatment.

Another 24 women with hyperandrogenism were treated with 2 mg of dexamethasone daily for 3 days. Blood was drawn before treatment and after 3 days of dexamethasone.

Finally, seven women with hyperandrogenism were treated with 0.5 mg of dexamethasone daily for 3 months. Blood samples were collected before and after 3 months of dexamethasone.

All blood samples were collected between 8 AM and 10 AM.

Assays. 11\beta-Hydroxyandrostenedione was measured in serum as previously described by Fiet et al.5 In brief, 0.2 ml of serum, to which 1000 to 1200 disintegrations per minute of tritiated 11β-A was added to monitor procedural losses, was extracted with diethyl ether; the extract was subjected to celite column partition chromatography. Elution of 11B-A was carried out with 70% (vol/vol) benzene in isooctane. The 11β-A fraction was redissolved in 0.7 ml of assay buffer; 0.2 ml aliquots were taken in duplicate for quantification by radioimmunoassay (RIA), and a 0.2 ml aliquot was counted to determine procedural losses. The 11β-A RIA uses tritiated 11β-A as radioligand, and an antiserum raised in rabbits against 68,118-dihydroxy-4-androstene-3,17-dione-6β-hemisuccinate-bovine serum albumin. Both the radioligand and antiserum were prepared as described previously by Putz et al.6 The linear range of the standard curve was 500 to 3.9 pg/tube. Separation of antibody-bound and unbound 11β-A was achieved with dextran-coated charcoal.

Reliability of the 11β-A RIA was determined as follows: Accuracy was assessed by measuring 11β-A in serial dilutions (1:1, 1:2, 1:4, 1:8) of pooled serum from women (undiluted serum concentration 7.8 ng/ml). Linear regression analysis of the 11\u00bb-A concentrations measured (y) versus the expected 11β-A concentrations yielded the following equation and correlation coefficient: y = 1.17x - 0.24; r = 0.999(n = 7). The assay precision was determined at a pooled serum concentration of 2.15 ng/ml. The intraassay and interassay coefficients of variation were 11.0% (n = 7) and 12.0% (n = 18), respectively. The specificity of the 11β-A antiserum was previously characterized.6 In our assay system the cross-reactivity of the antiserum with several important steroids was androstenedione, 11.2%; testosterone, 0.04%; cortisol, 0.13%; and DHEA, 2.3%. Because our 11β-A RIA uses an efficient chromatographic step to isolate the 11B-A fraction, we expect only minimal interference by other steroids in the assay. The practical sensitivity of the 11β-A RIA was calculated to be 100 pg/ml on the basis of the lowest reliable standard curve concentration (3.9 pg per tube), an assay factor of 17.5, and an average procedural recovery of 70%.

Serum levels of DHEA, androstenedione, and tes-

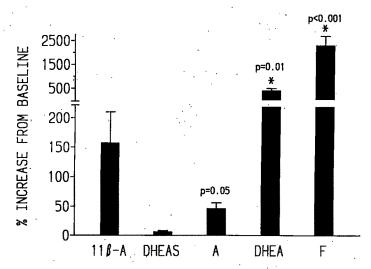

Fig. 2. Percent increase from baseline levels (mean \pm SEM) for 11 β -A, DHEAS, and rostenedione (A), DHEA, and cortisol (F) after corticotropin administration (0.25 mg intravenously) in women with hyperandrogenism (n = 16).

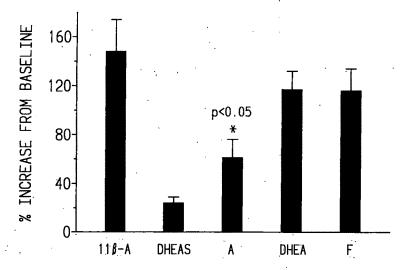

Fig. 3. Percent increase from baseline levels (mean \pm SEM) for 11 β -A, DHEAS, androstenedione (A), DHEA, and cortisol (F) after corticotropin-releasing factor stimulation (100 μ g of ovine corticotropin-releasing factor administered intravenously) in women with hyperandrogenism (n = 8).

tosterone were measured after extraction with diethyl ether and separation of steroids by Celite column partition chromatography, whereas DHEAS and cortisol were measured by direct RIA as previously described.⁷⁻¹²

Data analysis. The data from this study are reported as mean \pm SEM. Statistical tests included regression analysis by the method of least squares and the Student t test. The level of significance was 0.05.

Results

Serum levels of 11 β -A and DHEAS in normal women and women with hyperandrogenism are depicted in Fig. 1. Mean levels of both 11 β -A and DHEAS were approximately two times higher in the women with hyperandrogenism (2.69 \pm 0.16 ng/ml and 3.10 \pm 0.17

 μ g/ml) compared with the normal women (1.21 ± 0.07 ng/ml and 1.68 ± 0.16 μ g/ml). Fifty-seven percent of the subjects had elevated levels (2 SD above the mean value of the normal range) of DHEAS, that is, >2.8 μ g/ml, whereas 65% of the patients had elevations of 11β-A (>2.0 ng/ml).

Regression analysis of serum 11β -A levels versus DHEAS levels showed no correlation either in the normal women (r = 0.29); p = 0.15) or in the women with hyperandrogenism (r = 0.12; p = 0.28).

After corticotropin stimulation, 11β -A levels increased above baseline values by $157\% \pm 53\%$ (Fig. 2). This increase was significantly greater than the androstenedione and DHEAS responses, which were $46\% \pm 10\%$ (p=0.05) and $6\% \pm 2\%$ (p<0.001) above baseline values, respectively. However, the re-

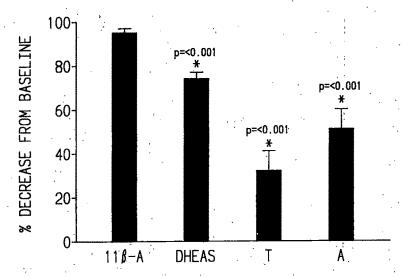

Fig. 4. Percent decrease from baseline levels (mean \pm SEM) for 11 β -A, DHEAS, testosterone (T), and androstenedione (A) after treatment with 2 mg dexamethasone daily for 3 days in women with hyperandrogenism (n = 10).

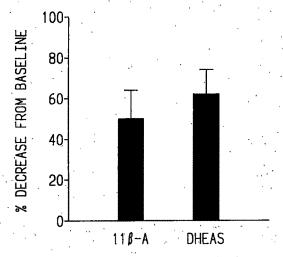

Fig. 5. Percent suppression from baseline levels (mean \pm SEM) for 11 β -A and DHEAS after treatment with 0.5 mg of dexamethasone daily for 3 months in women with hyperandrogenism (n = 7).

sponses of DHEA and cortisol were 416% \pm 80% and 2326% \pm 371% above baseline values and were significantly greater than the response of 11 β -A (p = 0.01 and p < 0.001), respectively.

With corticotropin-releasing factor, 11β -A was increased by $148\% \pm 26\%$ (Fig. 3). This was not only higher than the androstenedione response $(61\% \pm 15\%; p < 0.05)$ but also higher than the responses of DHEA and cortisol $(117\% \pm 15\%)$ and $116\% \pm 18\%$, respectively). The responses of the DHEA and cortisol, however, were not significantly different from the response of 11β -A.

Use of 2 mg of dexamethasone per day for 3 days

Table I. Sensitivity and specificity calculations for identifying dexamethasone sensitivity (adrenal gland component)

Marker	Se	nsitivity (%)	Specificity (%)	
DHEAS	. ' '	50	47	
11 β -A		83	63	

suppressed androstenedione and testosterone by $51\% \pm 9\%$ and $32\% \pm 9\%$, respectively (Fig. 4). These responses were not as great as the suppression of 11β -A (95% ± 2%; p < 0.001) or DHEAS (74% ± 3%). However, the 11β -A response was significantly greater (p < 0.001) than the response of DHEAS.

With long-term dexamethasone suppression with 0.5 mg of dexamethasone daily for 3 months, there was no difference between the 11 β -A and DHEAS responses (50% \pm 14% and 62% \pm 12%, respectively) (Fig. 5).

In both the stimulation and suppression studies, linear regression of the percentage of change of 11β-A or DHEAS versus baseline levels of the measured steroids showed no correlation (data not shown).

The sensitivity and specificity of 11β -A and DHEAS were calculated, and the values are shown in Table I. For these calculations we assumed that short-term dexamethasone suppression can be used to distinguish those hyperandrogenic women who have excess adrenal androgens. Therefore the subjects in the short-term dexamethasone study were divided into those who were dexamethasone sensitive (suppression of androstene-dione and testosterone was >60%; n=6) and those

who were dexamethasone insensitive (suppression of androstenedione and testosterone was <60%; n=18). 11β-A showed a greater sensitivity and specificity than DHEAS.

Comment

The results of this study demonstrate that 11B-A is a good marker of adrenal androgen production and may be useful in identifying those women with hyperandrogenism whose source of androgen excess is the adrenal gland. Among the group of women with mixed hyperandrogenism, DHEAS and 11B-A were elevated in 57% and 65% of the subjects, respectively. Because these percentages are not statistically different, we may conclude that in this study 11B-A is at least as valuable as DHEAS, which has been used as a specific marker. of adrenal androgen excess for some time.

On the basis of the responses of 11β-A and DHEAS to corticotropin-releasing stimulation and to short-term dexamethasone suppression, 11β-A appears to be a more sensitive marker than DHEAS for dynamic tests of adrenal gland function. One explanation for this finding may be related to the large pool of DHEAS. Additionally the pathway to the formation of 118-A may be more sensitive to stimulation than the pathway to the formation of DHEAS. 11B-A appears to be formed from androstenedione by the A5 pathway.13 However, the degree of suppression of 11β-A and DHEAS by long-term dexamethasone was similar.

Circulating levels of 11B-A and DHEAS did not correlate either in the normal women or in the women with hyperandrogenism. This finding suggests that 11β-A and DHEAS may reflect different patterns of

Although I 1β-A may be a more sensitive marker than DHEAS, there are potential disadvantages in the clinical application of 11B-A as a marker of adrenal androgen excess. One major disadvantage is that, unlike DHEAS, 116-A is subject to diurnal variation: Serum levels of 118-A are higher in the morning than at night. A second potential disadvantage of 11β-A originates from evidence that some 11β-A may be derived from the ovary. With selective venous catheterization, our preliminary data suggest that in some women the ovary may produce 11β-A.14 Another potential disadvantage of 11\beta-A is the cumbersome nature of the 11\beta-assay used in this study, in contrast to the simple and direct DHEAS assay. However, our 11β-A assay required extraction and chromatograph steps because of a lack of specificity of the 11\beta-A antiserum. A highly specific 11β-A antiserum that is used in a direct 11β-A assay is available commercially.4

Although 11β-A appears to have greater sensitivity and specificity than DHEAS (Table I), these data need to be placed in the proper perspective because the values are based on the use of the short-term dexamethasone suppression test and on a small number of subjects. We have previously shown that DHEAS is a poor predictor of this test result.15 Unfortunately there is no good criterion for establishing that a patient has adrenal androgen excess. The sensitivity of androgens to dexamethasone suppression is only one measure of dynamic adrenal androgen secretion.

Because our data suggest different secretion patterns of 11β-A and DHEAS, it is possible that both markers are required to distinguish those women with hyperandrogenism whose source of excess androgens originates from the adrenal gland.

Effects of peritoneal macrophages from patients with endometriosis on the proliferation of endometrial carcinoma cell line ECC-1

Ren-jie Zhang, MD,^a Robert A. Wild, MD,^a Diane Medders, BS,^a and Subba Rao Gunupudi, PhD^b

Oklahoma City, Oklahoma, and Sunnyvale, California

Endometriosis has been shown to be associated with increased number and activity of peritoneal macrophages. The peritoneal macrophage—conditioned media from 33 women with or without endometriosis were studied for their effects on an endometrial carcinoma cell line, ECC-1. The media from six of six stage III/IV cases demonstrated a mitogenic effect, which was blocked by an antibody to epidermal growth factor receptor. However, the conditioned media from seven of nine stage I/II cases and 14 of 18 normal women did not show a mitogenic effect. The difference between stage III/IV and the other two groups was significant (p < 0.01). The incorporation of tritium-thymidine was three times higher with the media from stage III/IV cases, as compared with that of controls. When purified cytokines were tested in the tritium-thymidine uptake assay, only epidermal growth factor—transforming growth factor- α was mitogenic on ECC-1, whereas tumor necrosis factor, interleukin-1, and platelet-derived growth factor had no effect. Thus peritoneal macrophages in patients with endometriosis may play an important role in the progression of endometriosis, and the noted effects could be mediated by epidermal growth factor or a related growth factor. (AM J OBSTET GYNECOL 1991;165:1842-6.)

Key words: Cytokine, epidermal growth factor, endometriosis, endometrial carcinoma cell

Endometriosis is a common disease in reproductiveaged women and is often associated with infertility. Recent studies¹⁻⁵ have shown that women with this disease have an increased number and activity of peritoneal macrophages. Growth factors (cytokines) from these macrophages or peritoneal fluid could decrease fertility by damaging gametes or embryos.^{6,7} However, whether the macrophages produce a cytokine(s) to promote the

environment by inhibiting these cells as a nonspecific inflammatory response is not clear. Stromal cell proliferation is stimulated by peritoneal fluid,⁸ so it is speculated that the development of endometriosis may be stimulated by a growth factor(s).

ectopic growth of endometrial cells or create a hostile

To determine whether a peritoneal macrophage-derived cytokine(s) from women with endometriosis has growth-promoting activity on endometrial epithelial cells, an endometrial epithelial cell line, ECG-1,9 was used for an in vitro proliferation study. To determine which cytokine has mitogenic activity on ECG-1, several commercial preparations of cytokines were compared. These preparations were tumor necrosis factor (TNF-α), interleukin-1 (IL-1), platelet-derived growth factor (PDGF), and epidermal growth factor (EGF)—transforming growth factor-α (TGF-α).

Material and methods

The collection and use of human tissue was approved by the Institutional Review Board of the University of Oklahoma Health Science Center. Peritoneal fluid was obtained from 15 patients with laparoscopically staged endometriosis (Revised American Fertility Society classification, 1985). Nine were stage I/II and 6 were stage III/IV. Of 9 with stage I/II, 7 were infertile; of 6 with stage III/IV, 4 were infertile. Of 18 fertile women undergoing sterilization without endometriosis, 5 had adhesions and 13 had a normal pelvis discovered at surgery; 8 were in the follicular phase and 10 were in the luteal phase of the cycle. Of 9 with stage I/II, 4 were in the follicular phase and 5 were in the luteal phase. Of 6 stage III/IV endometriosis patients, 3 were in the follicular phase and 3 were in the luteal phase.

Macrophages were isolated from peritoneal fluid by layering 1:1 diluted samples over Ficoll-Paque (Pharmacia LKB, Piscataway, N.J.) gradients and centrifuged at 400g at 18° to 20° C for 30 minutes. The macrophage fractions were washed twice with Hanks' balanced salt solution, spun at 60 to 100g for 10 minutes, and then resuspended in Dulbecco's modified Eagle's-high-glucose medium (Hazleton, Denver, Pa.) with 0.2% lactalbumin hydrolyzate (Gibco, Grand Island, N.Y.). The suspension was plated at 7.5 × 10⁵ cells per well in the 1.5 cm diameter tissue culture wells (Falcon, Los Angeles) for 1 hour. At the end of preincubation >90% of the cells were adherent. There was no difference in adherence between macrophage suspensions. The nonadherent cells were removed, and the media were then replaced with 1.5 ml of control medium, Dulbecco's modified Eagle's medium-nutrient mixture F-12 Ham with 1% fetal bovine serum (Sigma, St. Louis), and incubated as an adherent monolayer for 24 hours in 5% carbon dioxide at 37° C in a humidified incubator. Cell viability was assessed by microscopic visualization of cell morphologic types and adherence. Macrophages represented >90% of all the cells stained by Wright-Giemsa. The macrophage-conditioned media were collected, spun at 1500 rpm at room temperature for 10 minutes, and stored at -20° C until use.

A clonal continuous monolayer of the human endometrial carcinoma cell line ECC-1, which was derived from the well-differentiated estrogen-sensitive tumor EnCa-101 grown in nude mice, was used for this study because of the close similarity between the endometrial epithelial cells and ECC-1 cells. $^{9.11}$ The ECC-1 cells were plated in the 96-well tissue culture plates (Corning Glass Works, Corning, N.Y.) at a density of 1.5×10^5 per well and grown to 70% confluence in nutrient mixture F-12 Ham with 10% fetal bovine serum. The nutrient mixture F-12 Ham was supplemented with glucose 0.4 mg/ml (Sigma), insulin 0.2 U/ml (Collaborative Re-

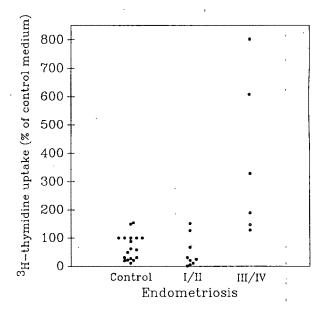

Fig. 1. Effect of macrophage-conditioned media from patients with and without endometriosis on tritium-thymidine incorporation of ECC-1 cells. Cells were harvested 24 hours after exposure to macrophage-conditioned media or control media. Difference of DNA synthesis between treatment with macrophages from patients with stage III/IV endometriosis versus other two groups is highly significant (p < 0.01).

search Inc., Bedford, Mass.), human transferrin 25 μg/ml (Sigma), cholera toxin 2.5 ng/ml (Sigma), estradiol 0.2 ng/ml (Sigma), 1% Pen/Strep mixture (Gibco), and L-glutamine 143 μg/ml (Gibco). Two days after plating, the serum-enriched media were replaced by control media (Dulbecco's modified Eagle's medium-nutrient mixture F-12 Ham, 1% fetal bovine serum) for 18 hours before addition of the macrophage-conditioned media or media supplemented with various concentrations of recombinant human TNF-α (Amgen, Thousand Oaks, Calif.), IL-1 (Accurate Chemicals, Westbury, N.Y.), PDGF (PDGF-BB, Genzyme, Boston), EGF (Genzyme), or TGF-α (Gibco). The cells were then continuously incubated for another 24 hours.

In another set of experiments ECC-I cells were preincubated with a monoclonal antihuman EGF receptor antibody (10 µg/ml, Genzyme) for I hour. Then control medium, EGF 10 ng/ml in control medium, or macropahge-conditioned medium from five patients with stage III/IV endometriosis was added to ECC-I cells, and the cells wre incubated for 24 hours. Appropriate controls were run without pretreatment with the monoclonal antibody.

Tritium-thymidine (ICN, Irvine, Calif., $0.1~\mu Ci$ per well, 10~Ci/mmol/L) was added 6 hours before the cells were harvested. The cell cultures were terminated with a semiautomatic cell harvester (Cambridge Technology, Watertown, Mass.). Incorporation of the radioactivity

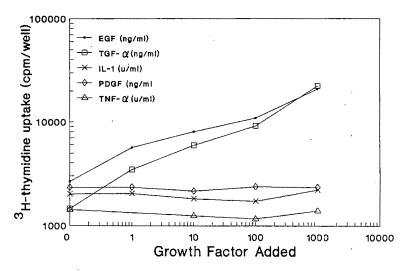

Fig. 2. Dose-dependent effect of cytokines on tritium-thymidine uptake by ECC-1 cells. EGF-TGF-α promoted tritium-thymidine uptake in a dose-dependent manner, but IL-1, PDGF, and TNF-α did not.

into cellular deoxyribonucleic acid (DNA) was measured by liquid scintillation counting.

To evaluate the effect of several cytokines on cell viability, total cell number, and cellular protein synthesis, ECC-1 cells were cultured in 1.5 cm diameter tissue culture plates at a concentration of 3×10^5 per well. Again, after the cells reached 70% confluence, they were subsequently incubated in control medium for 18 hours. The media were replaced with media supplemented with EGF (10 ng/ml), TNF- α (10 U/ml), IL-1 (10 U/ml), or PDGF (50 ng/ml) and incubated for 24 hours. Cell viability was then tested by trypan blue exclusion. Total cell numbers were counted on a hemocytometer, and protein concentrations were determined by protein assay (Bio-Rad, Richmond, Calif.).

The Wilcoxon rank-sum test was used for comparison of the mitogenic activities by macrophages from different patient groups.

Results

Macrophage-conditioned media from 6 of 6 patients with stage III/IV endometriosis demonstrated mitogenic activity to the target cell, ECC-1. Seven of 9 with stage I/II and 14 of 18 without the disease did not have the mitogenic effect (Fig. 1). The difference between stage III/IV and the other two groups was highly significant (p < 0.01). The incorporation of tritium-thymidine by the target cells was threefold higher with the medium from the stage III/IV patients as compared with that from the controls. There was no significant difference in mitogenic activity between the macrophage-conditioned media from endometriosis stage I/II and controls.

The mitogenic effect of EGF-TGF-α on target cell

DNA synthesis was dose dependent at 1 to 1000 ng/ml. In comparison, TNF- α (1 to 1000 U/ml), IL-1 (1 to 1000 U/ml), or PDGF (1 to 1000 ng/ml) showed no effect (Fig. 2). Viability of cells was >95% after the incubation period with the cytokines. Increases in total cell count and protein content were found only with the EGF (10 ng/ml) treatment, not with IL-1 (10 U/ml), TNF- α (10 U/ml), or PDGF (50 ng/ml) (data not shown).

Monoclonal anti-EGF-receptor antibody (10 μg/ml) caused >50% inhibition of the mitogenic activity of EGF (10 ng/ml, Fig. 3, B) and of macrophage-conditioned media from five of five patients with stage III/IV endometriosis (Fig. 3, C to G). The monoclonal antibody by itself had no significant effect on mitogenic activity (Fig. 3, A).

Comment

The association between endometriosis and an increase in the number and activity of peritoneal macrophages has led investigators to question whether these macrophages play an important role in the pathogenesis of the disease. Cytokines derived from peritoneal macrophages of patients with endometriosis produce different effects on various target cells. They have a proliferative effect on lymphocytes, lymphoma cells, and 3T3 fibroblasts; the mediator is thought to be IL-1, PDGF, or fibroblast growth factor.¹²⁻¹⁴ But cytokines have a cytolytic effect on L929 fibroblasts and WEHI-164 fibrosarcoma cells, which are TNF-α-sensitized target cells.^{15, 16} Peritoneal fluid from patients with endometriosis has been shown to stimulate the proliferation of human endometrial stromal cells.⁸

To study the effect of macrophage-derived cyto-

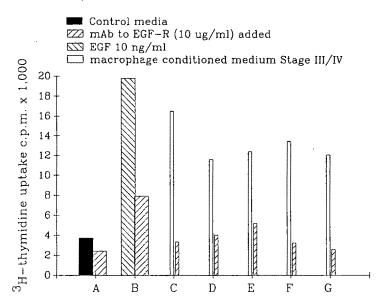

Fig. 3. Neutralization of monoclonal anti-EGF-receptor antibody (mAB to EGF-R) on ECC-1 cells. mAB to EGFR was added to control medium (A), EGF 10 ng/ml (B), or macrophage-conditioned media from patients with stage III/IV endometriosis (C to G). Antibody caused >50% inhibition of mitogenic activity of commercially obtained EGF and of macrophage-derived media from five patients with endometriosis. Antibody by itself had no significant effect on mitogenic activity (A).

kine(s) from patients with endometriosis on endometrial epithelial cells, the ECC-1 cell model was used, because an adequate number of purified epithelial cells from human endometrial tissue could not be grown. The ECC-1 cells are well-differentiated homogeneous epithelial cells that are cytokeratin positive (epithelial cell marker) and vimentin negative (stroma cell marker) by immunohistochemical methods.9 We have shown that antiendometrial antibodies from patients with endometriosis react with both endometrial glandular epithelial cells and ECC-1 cells but not with endometrial stroma cells.10 The close physiologic similarity between endometrial epithelial cells and ECC-1 cells is observed in their response to estrogen, progesterone, and interferon gamma.9, 11

Macrophage-conditioned medium from patients with stage III/IV endometriosis stimulated ECC-1 cell proliferation. Furthermore, a monoclonal antibody to EGF receptor blocked the mitogenic effect of the macrophage-conditioned medium. Because the macrophages were cultured in the absence of exogenous stimulants in vitro, these macropahges were likely to have been stimulated in the peritoneal cavity of the patients before they were studied. Therefore it is reasonable to speculate that, in the normal pelvis or in milder stages of endometriosis, the activity and secretion of macrophages might not favor the growth of ectopic endometrial epithelial cells. However, during the progression of endometriosis, as the disease becomes more severe, macrophages might receive sufficient stimuli to

be altered and reach certain levels of maturation. The macrophages might then secrete growth-stimulating substances into the peritoneal cavity, to which the ectopic cells of endometrial origin exhibit stimulated growth activity. One of the mediators might be related to EGF-TGF-α or a cytokine that reacts with the EGF receptor:

Among the tested commercial cytokines, EGF-TGFα was found to enhance proliferation, but TNF-α, IL-1, and PDGF did not. EGF and TGF-α are significantly homologous 17, 18 because they bind the same receptor. 19 Both are potent mitogens for a variety of cultured cells. In vitro, the proliferation of mouse uterine epithelial cells is enhanced by EGF but not by PDGF, fibroblast growth factor, or nerve growth factor.20 The receptor for EGF has been found in the rat uterus21 and in stromal and glandular epithelial cells of the human uterus. EGF is thought to be essential for growth of normal and neoplastic endometrium.22 Induction of transcription and secretion of TGF-α by activated human monocytes has been reported recently.23 However, it is not known whether macrophages produce EGF.

Peritoneal macrophage-derived cytokine(s) from patients with advanced stages of endometriosis and commercial EGF-TGF-α proliferated the endometrial epithelial cell line ECC-1 in vitro. These results suggested that the mediator in macrophage-conditioned media might be related to EGF-TGF-a. However, the mitogenic effect from the macrophage-conditioned medium, which was blocked by antibody to EGF receptor, could be due to other factors that work in synergy with EGF or to another factor that binds to EGF. Identification of these specific mediator(s) is currently under investigation.

We thank Dr. P. G. Satyaswaroop for the generous gift of the ECC-1 cell line. We thank Dr. Reichlin, Mr. J. M. Ojago, and Dr. M. Hill for technical advice.

Radioestrogens have potential as adjunct therapeutic agents against ovarian carcinomas, because selected radionuclides can deposit lethal doses of radiation to tumor cells and many ovarian carcinomas and their metastases express estrogen receptors. Because intraperitoneal administration is a possible approach, we investigated absorption from the peritoneal cavity of a radioiodoestradiol after intraperitoneal application in rats with and without ovarian tumors and ascites and compared the distribution of the radioactivity with that obtained after intravenous injection. In the absence of ascites, 70% of the intraperitoneal dose was cleared into the intestine within 2 hours after injection, indicating fast absorption from the peritoneal cavity. In the presence of ascites, clearance of intraperitoneal radioiodoestradiol was considerably slower; at 2 hours after injection, 50% of the injected dose remained in the ascites, mostly as radioiodoestradiol. Uptake of radioactivity in estrogen receptor—rich tissues, e.g., uterus, after intraperitoneal injection was high (about 20:1 over blood), regardless of the presence of ascites, but moderately lower than that observed after intravenous injection of radioiodoestradiol. (AM J OBSTET GYNECOL 1991;165:1847-53.)

Key words: Radiopharmaceutical, radioiodoestradiol, ovarian tumor, ascites, clearance

A recent report on the specific sequestration of a radiolabeled estrogen receptor ligand, 16α -[123 I]iodo- 17β -estradiol ([123 I]E $_2$), in estrogen receptor-rich tumors in man in vivo provided data for imaging of breast tumors and their metastases 1 that highlight the potential for application of radiolabeled sex steroid receptor ligands as pharmaceuticals. $^{2-6}$ In addition to being useful for imaging, iodoestrogens have been shown to cause selective cytotoxicity in estrogen receptor-rich cells in vitro. $^{7-9}$ This supports their potential for therapy. Use of radiohalogenated receptor ligands, especially those with short-range emissions (Auger electrons), in therapy is predicted not to compromise the use of established therapeutic modalities. $^{10-12}$

Ovarian carcinomas and their metastases express estrogen receptors in approximately half of the cases seen clinically, even after chemotherapy.^{18, 14} Therefore radioestrogens may offer an option as adjunct therapeu-

tic agents. Ovarian carcinoma is an intraperitoneal disease in most instances; therefore intraperitonal application of pharmaceuticals is considered an appropriate therapeutic approach.^{15, 16} We demonstrated recently that [125I]E2 given intraperitoneally is rapidly cleared from the peritoneal cavity with a half-time of approximately 30 minutes and that this route of administration results in high receptor-specific uptake in estrogen receptor-rich tissues.37 However, ovarian cancers are often accompanied by ascites. This raises the question whether the presence of ascites would affect the distribution and clearance of radiosteroids given intraperitoneally. To study this possibility, we compared organ uptake and excretion of [125I]E2 after intraperitoneal instillation into healthy female rats and into rats with ovarian tumors and ascites. We also compared the results to those obtained after intravenous injection.

Material and methods

Radiochemical purity and chromatography. Our approach for ensuring radiochemical purity and preparation of [125 I]E₂ (specific activity about 2000 Ci/mmol; Biomedical Products, Overland Park, Kan.) was adapted from the routine procedures we used when [125 I]E₂ is used for Scatchard plot and saturation analyses to characterize estrogen receptors for clinical purposes in specimens of breast cancer. On the day of use, chromatography on Sephadex LH20 (Pharmacia Fine Chemicals, Piscataway, N.J.) in a solvent system of ben-

zene/methanol (9:1, vol/vol) was performed to repurify and establish the radiochemical purity of the [125I]E₂. Approximately 0.2 ml of the benzene/methanol solution (9:1; vol/vol; the solvent mixture in which we held the [125I]E2 after receipt from the manufacturer) that contained sufficient radiopharmaceutical for the day's experiments was loaded onto a small (1.5 ml volume) Sephadex LH20 column held in a glass insulin syringe. Solvent (benzene/methanol; 9:1; vol/vol) was then added in 0.5 ml volumes each time that the solvent completed flowing through to the level of the column top. Fractions of 0.5 ml were collected and counted on a gamma counter. The three highest counting fractions corresponding to the peak for authentic [125I]E2 (usually including the fifth milliliter) were pooled, the solvent was evaporated under a stream of nitrogen, and then a small volume (0.020 to 0.050 ml) ethanol was used to resuspend the [125I]E2 that was subsequently diluted with distilled water, physiologic salt solutions, or the recipient's serum to an appropriate volume for injection.

Animal treatments and collection of specimens. All manipulations in animals were performed while they were under ether anesthesia.

Ovarian tumors were induced in rats (U-strain, Swedish) by autologous transplantation of the ovaries into the spleen. 18 The animals used in our experiments were about 20 months old and had easily palpable intraabdominal ovarian tumors (granulosa-theca cell tumors) and ascites. Because of delays caused by extremely cold weather and animal health care issues for international shipments of animals, of 12 rats initially prepared for developing tumors in Sweden, only four survived in adequate condition to be injected with [125I]E2 in the United States. Accrual of data over multiple time points was made possible by techniques for collecting multiple samples of blood by cardiac or venipuncture. Similarly, ascites fluid was sampled in small volumes by intraperitoneal taps. After intraperitoneal injection with [125I]E2, rats were held in small cages with filter paper over the floor. The filter paper was changed at selected time intervals, and the spots of urine cut out for counting. Thus, with rats with tumors, instead of sometimes relying upon killing the animals for each time point, we made use of repetitive sampling. This was also done with tumor-free rats that received the [125I]E2 intraperitoneally to ensure data that could be compared. Within each treatment, results were consistent and compelling and allowed interpretation of biologic phenomena that could be reproduced with almost certainty by other investigators.

Intraperitoneal injections of [125 I]E₂ (20 μ Ci, 1 ml serum) were performed in 10 healthy rats (Sprague Dawley, about 270 gm body weight) without tumors and in four rats with ovarian tumors and ascites (about 380 gm body weight). Blood was drawn by cardiac puncture

at selected time intervals. To estimate the amount of radioactivity excreted by the kidneys, we sampled the urine by collection on filter paper placed at the bottoms of the animal cages. To test for differences in organ uptake of [125I]E2 after intraperitoneal and intravenous administration, we also injected [125I]E2 (25 µCi, 200 µl serum) into the tail veins of 20 healthy adult rats (Sprague Dawley, about 270 gm body weight). These rats, as well as those injected intraperitoneally, were killed at selected time points, and then organs, including the contents of the intestines, were sampled and weighed. To assess the receptor mediation of organ uptake of [125I] E2, we blocked estrogen receptor in vivo by injecting some animals subcutaneously with 500 µg diethylstilbestrol I hour before administering the radiopharmaceutical.

Tissue handling and counting of radioactivity to assess biodistribution. Radioactivity was measured in organs, organ contents, body fluids, and urine. The individual organs of the body were extirpated in their entirety, placed in appropriately sized plastic bags or small plastic tubes, and immediately snap-frozen in liquid nitrogen vapor. With respect to animals that received [125I]E2 intraperitoneally, to reduce error from contamination from intraperitoneal fluid that contained high levels [125I]E2 on the exterior of organs of the abdominal cavity, these organs were rinsed in ice cold saline solution, rapidly blotted to remove free moisture, and then the serosal surface was peeled off as much as possible. For the gut, the serosa was peeled off beginning on the mesometrial side, along the length of which a blunt probe was pushed to facilitate separation of the bowel tissues from the serosa. Organs were counted whole in a calibrated well-counter that was operated within its range for accurate counting rates. Corrections were made for background, for tissue volume absorption of radiation, and for geometry. The two latter correction calculations were established by saline solution-filled phantoms and the use of standards with known counts. Because the well y-counter had an opening of sufficient diameter, it was possible to briefly place an entire live animal in a plastic bag into the well counter for counting immediately after administering the radiopharmaceutical. If the count rate was too high, the animal was placed on a shield above the opening; the corrections for counting efficiency changes caused by differences in geometry were established with standards that contained known amounts of iodine-125 decay. This approach provided an accurate estimate of the injected dose that could be compared with the injected dose determined from counting the syringe, needle, and any tubing that were loaded with the dose for injection immediately before the injection, from which were then subtracted the counts remaining in the syringe and accessories immediately after the injection. Calculations for radio-

activity in the whole animal's blood were based on an assumption of a blood volume of 7% of body volume. as estimated from each animal's measured whole-body weight. Gastrointestinal tract contents from selected and measured segments were gently flushed three times with cold normal saline solution into vials. Usually the entire volume could be measured; however, in instances when the count rate was too high, aliquots were taken after thorough mixing to ensure homogeneous distribution of counts throughout the entire original volume. Alternatively, the geometry for counting was changed to a configuration for which the reduction in counting efficiency was known.

Blocking estrogen receptors in vivo. To assess the receptor mediation of organ uptake of [125I]E2, we blocked estrogen receptor in vivo by injecting some animals subcutaneously with 500 µg diethylstilbestrol (DES) I hour before administering the radiopharmaceutical.

Approaches for assessing metabolites. To obtain information about metabolic pathways of [125I]E2 in rats, we tested for the chemical form associated with the radioactivity in ascites and intestinal contents from rats with tumors with the following procedures. Ascites (300 μl) and contents from the upper small intestine (100 µl) were diluted in 1 ml 0.1 mol/L phosphate buffer, pH 11.0, mixed with benzene (vol/vol, 1:10), vortex blended for 10 seconds, incubated for 1 hour, and centrifuged for 30 minutes at 1200 to 1500 g for removal of particles from the aqueous phase and extraction of radiolabeled moieties soluble in organic solvents. After three extractions, we subjected 100 µl of the aqueous phase to aqueous column chromatography (Sephadex G15, Pharmacia) in 0.1 mol/L phosphate buffer, pH 11.0 (column volume, 8 ml; column diameter, 0.85 cm; flow rate, 40 ml/hour; fraction size, 2.5 ml). This aqueous phase chromatography was performed to learn how much to the radioactivity that remained in the aqueous phase after organic solvent extraction could be attributed to free 125I and how much to watersoluble conjugates of [125I]E2. Free 125I elutes soon after a single volume equal to the column void volume has passed; glucuronide and sulfate conjugates of iodoestradiol elute after passage of solvent volumes of two or more times the void volume.

To establish whether the radioactivity in the aqueous phase consisted of glucuronides and sulfates, we incubated samples of the aqueous extracts (100 µl) with glucuronidase (from Escherichia coli, Sigma Chemical Co., St. Louis; 475 U/ml in 0.1 mol/L phosphate buffer, pH 6.8) or sulfatase (from limpets, Patella vulgata, Sigma; 3.7 U/ml in cold 0.25% sodium chloride, pH 5.0) at 37° C for 2 hours. After incubation, samples were extracted twice with benzene. Radioactivity recovered in the benzene extract would represent conversion from a polar to a nonpolar moiety by enzymatic hydrolysis and thereby establish the existence of iodoestrogen conjugates.

Benzene was evaporated from the ascites extracts. The residues were resuspended in 0.5 ml benzene/methanol (9:1) and subjected to column chromatography on Sephadex LH20 (Pharmacia) column volume, 10 ml, column diameter, 0.85 cm; flow rate, 8 ml/hour; fraction size, 1 ml) in a benzene/methanol (9:1) solvent system, which yields separation of phenolic steroids.19 To learn whether organic moieties of radioactivity that were separated by column chromatography represented the original [125I]E2, we compared their elution volumes to that of [125I]E2.

In addition, these moieties were subjected to a modified dextran-coated charcoal estrogen receptor-binding assay.20 We set the conditions such that estrogen receptor (rabbit uterine cytosol that contained estrogen receptor >300 fmol/mg of soluble cytosol protein) was in excess and the sample to be analyzed was the source of putative radioligand.

Results

In healthy rats, blood concentrations of radioactivity that had been injected intraperitoneally reached a maximum of about 0.1% of the injected dose per milliliter after 30 minutes, which decreased to 0.06% ml within 4 hours after injection (Fig. 1, A). The uptake of radioactivity in the estrogen receptor-rich uterus was high and ranged from 1% to 2% of the injected dose per gram of organ weight during the first 3 hours after injection; however, the level of radioactivity in the uterus was markedly lower after 4 hours (Fig. 2, A). Uterine uptake was blocked by pretreatment with DES. The levels of radioactivity in estrogen receptor-poor organs were generally much lower than those found in the uterus, except in the liver, omentum, and thyroid, and could not be blocked with DES. The thyroid level was high after 2 and 4 hours (Fig. 2, A). The radioactivity injected into the peritoneal cavity was rapidly cleared into the intestine. The small intestine contained 70% and >80% of the injected dose at 2 and 4 hours after injection, respectively. Radioactivity in the colon, however, was low at all times up to 4 hours after intraperitoneal injection (Fig. 1, B). Excretion of radioactivity in urine was delayed compared with secretion into the intestine; it remained <2% of the injected dose during the first 4 hours after injection (Fig.

In rats with ovarian tumors (range of tumor weights, 7 to 15 gm) and ascites (range of volumes, 50 to 110 ml), clearance of [125I]E2 from the peritoneal cavity was considerably slower. At 2 hours after injection, 50% of the injected dose remained in the ascites (Fig. 1, B). More than 90% of this activity was associated with an organic compound that cochromatographed with [125] E2 in the Sephadex LH20 system (Fig. 1, D) and

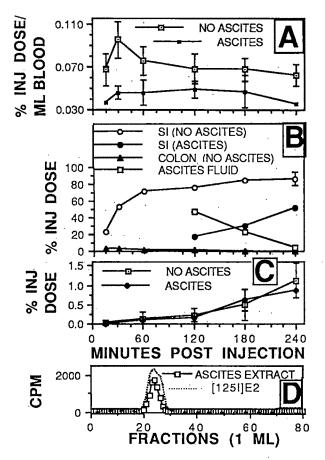

Fig. 1. Concentration of radioactivity in blood (A), fraction of radioactivity in ascites, and contents of small intestine (SI), and colon (B), and fraction excreted in urine (C) as function of time after intraperitoneal injection of [125 I]E $_2$ into rats with and without ascites. Elution patterns on Sephadex LH20 columns of [125 I]E $_2$ and of radioactivity that was extracted with benzene from ascites taken 2 hours after intraperitoneal injection (D).

bound to estrogen receptor in vitro (data not shown), consistent with its remaining [125I]E2. It took 4 hours until most of the radioactivity was cleared from the peritoneal cavity (Fig. 1, B). As in the healthy rats, low levels of radioactivity were measured in the colon content (data not shown). With the exception of a lower uptake by the omentum, the levels of radioactivity in organs, including the uterus, were similar to that observed in healthy rats. However, in contrast, uptake in the uterus, which was blocked by nonlabeled DES, remaining high at 4 hours after injection (Fig. 2, B). Ovarian tumors had a total uptake in the range of 2% to 3.5% of the injected dose, but this uptake was low on a tumor weight basis and was not altered by excess DES (Fig. 2, B). Blood levels of [125I]-label were below those seen in healthy rats and remained fairly constant for 3 hours after injection (Fig. 1, A). Approximately 20% and 50% of the injected dose of [125I]E2 was found in the small bowel at 2 and 4 hours after injection, respectively, consistent with prolonged retention of $[^{125}I]E_2$ in the ascites (Fig. 1, B).

As was determined by extraction and column chromatography (data not shown), the radioactive material in the intestinal contents did not include [125I]E₂ and contained <5% free 125I. The chemical form associated with the major portion of the intestinal radioactivity was not identified, but we found that it was not composed of [125I]-steroid conjugages that could act as substrates in our enzymatic digestions (i.e., neither glucuronides nor sulfates), because our digests did not release radioactivity that could be extracted in organic solvents (data not shown).

After injection of [125I]E₂ intravenously into healthy rats, uterine uptake was about twice that observed after intraperitoneal injection into healthy animals at the time points examined; uptake in other organs was comparable to that for intraperitoneal injection. The uterine content of radioactivity had decreased appreciably at 4 hours after intravenous injection (Fig. 3).

Comment

[125I]E2 administered intraperitoneally to healthy rats was rapidly absorbed from the peritoneal cavity, whereas absorption was delayed in rats with ascites. This difference is clearly seen in the different rates of clearance of the radioactivity into the intestine (Fig. 1). The high levels of radioactivity in the small intestine of healthy rats was found to be in the intestinal contents. Adsorption of radioactivity at the mesenteral surface of the bowel with retention in the gut lumen seems unlikely, because this would affect the entire bowel and high levels of radioactivity would then be expected also in the colon, but this did not happen. The delay in the secretion of the radioactivity into the intestine in rats with ovarian tumors can be attributed to delayed absorption from the peritoneal cavity rather than to failing liver function, because we found that a large fraction of the radioactivity was retained in the ascites (see Fig. 1, B). With liver failure, one would expect higher than normal accumulation in the liver or blood, something that did not happen.

Prolonged clearance of the radiopharmaceutical from the abdominal cavity in the presence of ascites may also occur in man. Because rats do not have sex hormone—binding globulin, this protein, which might be in ascites in man, is not responsible for the delay documented in our studies. Therefore, if the delay occurs in rats without sex hormone—binding globulin, it may be expected in humans also, who may have sex hormone—binding globulin in the ascites fluid. Possibly albumin in rat ascites fluid provides binding capability. It is important to appreciate before extending our studies on excretion patterns that only rudimentary data are available, and little is understood about differences

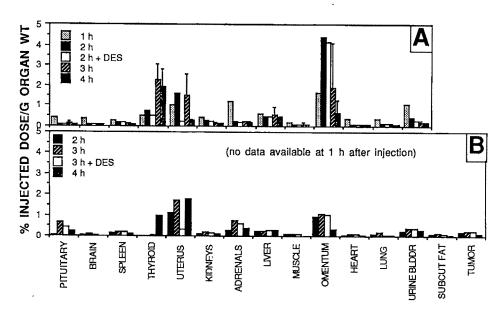

Fig. 2. Uptake of radioactivity in various organs at selected time points after intraperitoneal injection of $[^{125}I]E_2$ into rats without (A) and with (B) ascites.

in specific details of haloestrogen metabolism rat and man.

After intraperitoneal injection of [1251]E₂, high levels of radioactivity were seen in the omentum, especially in healthy rats. This uptake, which could not be blocked with DES, is most likely caused by direct absorption of the fat-soluble radioestrogen into the omentum, which consists mainly of fat. Similar results were reported after intraperitoneal injection of iodoestradiol into swine.¹⁷ The lower levels of radioactivity in the omentum in the rats with ovarian tumors is consistent with ascites affecting absorption of intraperitoneal radioestrogens.

The ovarian tumors took up radioactivity only at relatively low levels. This low uptake was predictable be-

cause these were theca granulosa cell tumors, which are known to contain and secrete steroids. The rat tumor model which we used is characterized by high levels of endogenous gonadotropins that probably result from low circulating levels of biologically active steroids, caused by the fact that the venous return from the steroid-secreting ovarian tissue transplanted to the spleen flows into the hepatic portal vein. As a result, the active steroids of the ovarian effluent are immediately conjugated in passage through the liver, and the steroidal bioactivity is lost. The high levels of gonadotropins stimulate high production and high levels of estrogens within the ovary. These estrogens occupy any estrogen receptor that might be present and block potential uptake of [1251]E₂. Most ovarian tumors seen clin-

ically, however, are not associated with a local excess of endogenous estrogens.

In the healthy animals, a major fraction of the radioactivity absorbed from the peritoneal cavity was rapidly cleared into the intestine. This finding is in accordance with earlier reports²¹ that, after intravenous administration of [125I]E₂ to rats, 50% to 70% of the radioactivity can be found in the intestinal contents within I hour, and that more than 80% of the injected dose is eventually removed in the feces. These authors reported that bile contained neither the original [125I]E₂ nor high amounts of free 125I and that enzymatic hydrolysis with glucuronidase or sulfatase did not release [125I]E₂ from bile.²¹ Their findings are supported by the results of our analyses of the radioactive material in the intestinal content.

Our data document that the onset of excretion of radioactivity into the urine is delayed considerably when compared with that into the intestine. This suggests that the radioactive metabolites of [125I]E₂ are not secreted primarily into the urine but undergo biliary clearance into the intestine. The delay in urinary excretion of radioactivity is consistent with the assumption that a major fraction of the radioactivity which finally appears in the urine was reabsorbed from the gut.

After intraperitoneal administration, [125I]E2 was available for estrogen receptor-mediated binding in receptor-rich organs, e.g., the uterus. The latter retained high levels of radioactivity for at least 3 hours. This finding is consistent with results in swine that were reported earlier.17 Intravenous injection of [125I]E2 resulted in moderately higher uterine concentrations of the radiopharmaceutical, perhaps because a significant amount of intraperitoneal iodoestradiol, after it is absorbed from the peritoneal cavity, is transported by the portal vein through the liver, which rapidly metabolizes iodoestrogens.22 Thus only a fraction of the administered radioactivity may enter the general circulation unmetabolized to be distributed throughout the body organs. Most of the estrogen receptor-mediated uptake in the uterus probably resulted from delivery through the circulatory system; radiopharmaceutical absorbed directly from the peritoneal cavity may have contributed only a fraction of the total uptake. However, the effective route of delivery may be reversed with an ovarian tumor, which metastasizes intraperitoneally as small tumor nodules or single cells, because the tumor calls in ascites take up radiohalogenated estrogens directly.23

The presence of ascites prolonged the absorption of [125I]E₂ from the peritoneal cavity but did not interfere with uptake of radioactivity in the estrogen receptor—rich uterus. Thus ascites appears to act like a depot

which could allow prolonged exposure of estrogen receptor—rich cancer cells in the abdomen to the radio-pharmaceutical. The prolonged opportunity for uptake could be expected to improve the cytotoxic potential of radiohalogenated estrogen receptor ligands against intraabdominal receptor-rich cancer cells because it would extend the time frame for formation of intranuclear receptor-ligand complex.

C-jun and jun-B oncogene expression during placental development

Lauren J. Dungy, MD, Tariq A. Siddiqi, MD, and Sohaib Khan, PhD Cincinnati, Ohio

During embryogenesis, growth and differentiation occur in a sequential, predetermined order suggesting that specific genes are turned on and off in a precise and well-regulated manner. Placental development, which is characterized by massive proliferation and differentiation of multiple cell types, must be similarly regulated. Early response protooncogenes, such as c-jun and jun-B, have been associated with both proliferation and differentiation of different cell types. In this study, using Northern blot analysis, we found that c-jun and jun-B expression occurred in human placentas throughout gestation. Maximal expression of c-jun occurred in early gestation, and maximal expression of jun-B occurred in late gestation. We speculate that peak expression of c-jun in human placenta at early gestation may be related to cytotrophoblastic proliferation and that peak expression of jun-B in late gestation may be related to further terminal differentiation of trophoblastic cells. (AM J OBSTET GYNECOL 1991;165:1853-6.)

Expression of c-jun is noted throughout gestational period shown. Maximal expression was identified in early gestation (5 to 14 weeks) by densitometric quantification.

a role in cytotrophoblastic proliferation and placental growth. We studied the temporal expression of these protooncogenes in human placentas to examine this hypothesis.

Material and methods

Collection of placental tissue. Placental tissue was obtained after curettage, spontaneous delivery, or cesarean section and was immediately placed in liquid nitrogen. Informed consent was obtained in all instances in accordance with the protocol approved by our institutional review board. Time frames of placental tissue studied were chosen to correlate with early, mid, and late gestation. Placental tissue obtained from 32 patients was used for analysis. Eight panels of total ribonucleic acid (RNA) from placental tissue of similar gestational age, ranging from 5 to 40 weeks' gestation, were studied with Northern blot analysis.

RNA isolation. Total RNA was isolated from the placental tissues according to the technique of Chomzynski and Sacchi.18 Approximately 2 gm of placental tissue was homogenized in 10 ml of extraction solution (4 mol/L guanidine thiocyanate, 25 mmol/L sodium citrate at pH 7.0, 0.5% sarcosyl, 0.1 mol/L 2-β-mercaptoethanol, 2 mol/L sodium acetate, and 10 ml phenol). The homogenate was mixed with chloroform/isoamyl alcohol (2 ml of 49:1 solution) and chilled on ice for 15 minutes. After centrifugation for 20 minutes at 10,000g at 4° C, the aqueous phase was removed and precipitated with one volume of isopropanol at -20° C for 2 hours. This was followed by a second centrifugation for 20 minutes at 10,000g and 4° C. The resultant pellet was dissolved in extraction solution (600 mm³) and precipitated with isopropanol (one volume) and sodium acetate (1/10 volume) at -20° C for approximately 2 hours. After centrifugation for 10 minutes at 4° C, the pellet was washed with 70% ethanol and vacuum dried for approximately 5 minutes. The pellet was then resuspended in diethyl pyrocarbonate-treated water. Total RNA concentration was quantitated by absorption spectrometry at 260 nm.

Northern blot analysis. RNA samples (50 and 100 μg) were resolved by electrophoresis on formaldehyde agarose gels and transferred to nitrocellulose membranes by towel blotting. The integrity and quantity of each RNA sample were ensured by staining the gel with ethidium bromide and visualizing the gel under ultraviolet transillumination. The filters were prehybridized in hybridization solution containing 10× Denhardt's solution, 0.1% sodium dodecyl sulfate, 100 μg/ml sin-

gle-stranded salmon sperm deoxyribonucleic acid, 50% deionized formamide, and a 5× solution of 3 mol/L sodium hydroxide and then hybridized in the same solution containing a phosphate 32-labeled human cjun or jun-B complementary deoxyribonucleic acid probe (1 × 106 cpm/ml) at 42° C overnight. After four washings (final wash in 1 × saline sodium citrate buffer with 0.1% sodium dodecyl sulfate at 55° C for 20 minutes), the filters were subjected to autoradiography. The position of 18S and 28S RNA was determined, and the bands that corresponded to the position of c-jun (3.2 and 2.7 kb) and jun-B (2.2 kb) were quantitated by scanning densitometry with a Hoefer GS 300 gel scanner (Hoefer Scientific Instruments, San Francisco).

Results

With Northern blot analysis using 50 and 100 µg samples of total RNA, we were able to identify c-jun and jun-B messenger RNA expression in human placentas throughout the gestational ages studied (between 5 and 40 weeks). Northern blot analysis of total RNA isolated from tissue between 6 and 40 weeks' gestation revealed c-jun expression throughout these time points. Detected levels of c-jun expression were greatest in early gestation (between 5 and 14 weeks). Further analysis of total RNA isolated from tissue samples ranging from 5 to 14 weeks' gestation revealed maximal expression at 5 and 6 weeks' gestation (Fig. 1). Fig. 2 represents the continuous scanning densitometry graph of a blot of equal amounts of total RNA isolated from placental tissue ranging from 6 to 40 weeks' gestation.

Expression of jun-B also occurred throughout gestation. Maximal levels of expression were detected later in gestation at 35 and 40 weeks (Fig. 3). Low to undetectable levels of expression were noted at early and mid gestation (between 5 and 20 weeks).

Comment

Several lines of evidence suggest a role for protooncogenes in cell proliferation and differentiation. The placenta exhibits massive proliferation and differentiation of multiple cell types during development. Knowledge of regulatory factors involved in these processes is limited, but experimental data that support a role for protooncogenes exist. Expression of protooncogenes has been described in placental tissues, and levels of expression of some protooncogenes have been shown to vary during the course of pregnancy. Expression of c-myc, for example, which has been associated with cytotrophoblastic proliferation, exhibits the highest levels in early gestation and a clear decline is seen before the end of pregnancy.14 The sis protooncogene also has been associated with cytotrophoblastic proliferation but is highly expressed throughout gestation. Expression of epidermal growth factor receptor, the cellular equivalent of the erb-B oncogene, increases throughout pregnancy and is believed to function in the maintenance of differentiation of syncytiotrophoblastic cells. 15

The expression of the different *jun* protooncogenes and the role of their gene products in cell proliferation and differentiation have been widely studied in different cell lines. To our knowledge, however, the expression of these genes has not been examined during human placental development. Because of their nuclear localization and their association with processes of cell proliferation and differentiation, the jun protooncogenes may participate in the regulation of growth and differentiation of placental tissues. Expression of jun messenger RNA has been identified in many cell lines, and an alteration of expression can be elicited when proliferation and differentiation are stimulated in these cells.16-18

Evidence exists that the regulation of different jun genes is not coordinate and that they may play distinct roles in regulation of cell growth. The relative amounts of each jun RNA vary in different cell lines and organs. 19 Although the amino acid sequence of the jun proteins is closely related, there are distinct regions of dissimilarity that have been conserved throughout evolution,19,20 which suggests that they may have distinctive biologic properties. Moreover, different levels of transcriptional activation of gene expression in response to serum growth factors have been demonstrated among the jun RNAs, which suggests that these genes may be regulated by unique controlling elements.19

The observations made in our study also suggest that the regulation of different *jun* genes is not coordinate during human placental development and that they may play distinct roles in regulation of placental growth. Although c-*jun* and *jun*-B expression was identified throughout gestation, maximal expression of these genes occurred at opposite spectra of placental development. Expression of c-*jun* messenger RNA was greatest in early gestational tissue (between 5 and 14 weeks); maximal expression occurred at 5 and 6 weeks' gestation. Conversely, *jun*-B messenger RNA expression in human placenta was greatest in late gestation at 35 and 40 weeks.

Placental growth is characterized by the proliferation and invasion of cytotrophoblastic cells; this is followed by coalescence of daugher cells in the syncytium.21 These processes predominate during early gestation. During this stage of placental development, we noted peak c-jun expression. Increased c-jun expression at this time may be functionally associated with the regulation of gene expression related to cell proliferation of cytotrophoblastic cells, as well as with the proliferation of elements of the villous mesenchymal core, including myofibroblasts and angioblastic cells. Absolute growth of the human placenta declines in late gestation; this decline begins at approximately 35 weeks, at which time cessation of cytotrophoblastic proliferation occurs.22 Maximal expression of jun-B was noted in late gestation; increased expression occurred at 35 and 40 weeks' gestation. This increase of expression at the stage of placental development during which cytotrophoblastic proliferation is absent may be associated with terminal differentiation of trophoblastic cells.

In summary, c-jun and jun-B protooncogene products have been identified as factors that regulate gene expression and that are associated with the processes of cell proliferation and differentiation. The different patterns of expression noted in different cell lines and in response to different inducing agents suggests that these genes play distinct roles in regulation of growth processes. The discordant patterns of expression of the two genes identified throughout gestation in our study by means of Northern blot analysis also suggest that these genes may regulate different gene processes during human placental development. The peak expression of c-jun in early gestation may be associated with cytotrophoblastic proliferation, and maximal expression of jun-B in the late stages of placental development may be related to terminal differentiation of trophoblastic cells. Identification of the spatial pattern of expression of these genes by means of immunohistochemical analysis or in situ hybridization will be of value in examining further the role of c-jun and jun-B in the regulation of trophoblastic cell growth and differentiation.

New monoclonal antibodies identify the glycoprotein carrying the CA 125 epitope

Timothy J. O'Brien, PhD, Lawrence M. Raymond, PhD, Gary A. Bannon, PhD, Danny H. Ford, Hildur Hardardottir, MD, Frank C. Miller, MD, and J. Gerald Quirk, Jr., MD, PhD

Little Rock and Fayetteville, Arkansas

CA 125 is an antigenic determinant located on the surface of ovarian carcinoma cells and elevated in the serum of >90% of patients with carcinoma. The antigen, derived from the ovarian epithelium, has been described as a mucinlike glycoprotein >200 kd. To date little is known of the metabolic regulation or expression of this antigen in either normal or neoplastic tissues. New monoclonal antibodies that we describe here recognize both unique and similar epitopes to OC 125. These reagents may allow for a more complete definition of the structure and expression of the CA 125 complex. These antibodies recognize high-molecular weight (>200 kd) subspecies and a lower-molecular-weight (68 kd) subspecies of the antigen and identify it in the cytoplasm and the extracellular matrix of CA 125—producing cells. (AM J OBSTET GYNECOL 1991;165:1857-64.)

Key words: CA 125, OC 125, monoclonal antibodies, immunoprecipitation, immunolocalization

CA 125 was discovered by Bast et al.1,2 with a monoclonal screen for tumor-specific antigens of hybridomas derived from mouse lymphocytes immunized to an ovarian cell culture line, OVCA433. The antigen is located on the surface of ovarian tumor cells with essentially no expression in normal adult ovarian tissue.3 It is expressed on the cell surface of tumor cells in culture and on ovarian tumor lesions. Significantly, CA 125 is also found in sera of patients with ovarian adenocarcinoma. It is, however, not exclusively in blood from patients with ovarian carcinoma but is also elevated in a significant percentage of sera obtained from patients with pancreatic carcinoma (about 50% of patients) and in liver, colon, and others (22% to 32%).1.4 It is now clear that CA 125 can be detected regularly on the tumor cell surface and in the serum of patients with serous cystadenocarcinoma of the ovary (>95%). Expression of this antigen occurs less frequently in endometrial and clear cell carcinomas, and essentially no expression is detected in mucinous cystadenocarcinomas. It may be expressed by endometrial, cervical, and mucinous cystadenocarcinomas of the ovary but is detected infrequently in the blood of these patients.

The presence of CA 125 in high concentrations in the serum of patients with ovarian adenocarcinoma has significantly altered the management of such patients. Even though CA 125 is not specific for ovarian carcinoma, it does nonetheless correlate directly with disease status (progression [increase], regression [decrease], and no change [constant]).2 Almost all ovarian cancer patients receive extensive chemotherapy, and CA 125 is used by many investigators as an indicator of a disease-free state.5-7 At second-look laparotomies it has been found that focal disease of <2 cm can be present without an elevated serum CA 125 level.8.9 Nonetheless increased serum concentrations of CA 125 precede clinical diagnosis of recurrent disease from 1 to 4 months. As a result, assay of this tumor marker is becoming a standard component of the care for patients with ovarian cancer. As previously indicated, CA 125 is not an exclusive product of ovarian cancer cells. Like many other tumor markers (e.g., α-fetoprotein and human chorionic gonadotropin), it also is expressed normally early in fetal development. Kabawat et al.3 demonstrated traces in fetal tissues; the antigen was localized to the amnion and derivatives of müllerian epithelium and coelomic epithelium (including the peritoneum, pleura, and pericardium). In adult tissues the monoclonal antibody OC 125 reacted with the epithelium of the fallopian tube, endometrium, and endocervix and has also been found expressed in the apocrine sweat glands and the mammary glands. 9. 10 Hardardottir et al. 10 have further indicated the presence of antigen dur-

ing fetal development in notochord, myocardium, pericardium, the mesonephric duct, the vitelline and allantoic ducts, and the amnion and periderm. Elevations of serum CA 125 levels in patients with endometriosis during menses and in early gestation further supports the notion that this antigen is expressed during normal growth and development. The presence of the antigen in abundance in breast milk, benign ovarian cyst fluid, and amniotic fluid further implicate CA 125 in normal cell growth and development. The presence of the antigen in abundance in breast milk, benign ovarian cyst fluid, and amniotic fluid further implicate CA 125 in normal cell growth and development.

To date little is known of the structure of this extracellular matrix molecule, and no indication of its function has been determined. The available data on the structure of CA 125 indicate that it is part of a largemolecular-weight, mucinlike glycoprotein complex that can be resolved to a 200 to 250 kd species on sodium dodecyl sulfate-acrylamide or agarose-acrylamide gels. The antigen is thought to contain a carbohydrate component, on the basis of the presence of sugar residues, buoyant density studies, and lectin-binding properties. However, the antigenic epitope recognized by OC 125 is considered to be peptidic in nature because of its sensitivity to proteases such as trypsin and V8 protease and its relative stability to glycosidases.20-22 We reasoned that understanding the structure and function of the CA 125 molecule depends both on the development of reagents to map protein domains and on cloning the CA 125 gene. Here we describe some new monoclonal antibodies that recognize both unique and common (or closely related) epitopes detected in the glycoprotein molecule that expresses the CA 125 determinant.

Material and methods

Immunization. CA 125 antigen derived from ascites fluid was partially purified (approximately 2000 U/µg protein) as previously described.17 The antigen was precipitated with alum according to the procedure of Hudson and Hay.23 The resulting precipitate was washed twice with a 15 µl volume of 0.01 mol/L phosphatebuffered saline solution with 0.15 mol/L sodium chloride, pH 7.2. The pellet was suspended in 50 µl of phosphate-buffered saline solution and maintained at 4° C until use. BALB/c mice were immunized by intraperitoneal injection of 20 µg alum-precipitated antigen in 100 µl phosphate-buffered saline solution containing 109 killed Bordetella pertussis organisms (Michigan Department of Health, Lansing, Mich.). After 4 weeks mice were challenged again by intraperitoneal injection of a 20 µg of soluble antigen in phosphate-buffered saline solution. Two weeks later the mice were challenged further with 20 µg of soluble antigen by intraperitoneal injection. Three days later spleens were harvested for fusion with mouse myeloma

Hybridomas. Fusion of immune mouse splenocyte

and 8-azo-guanine—resistant P3X63-Ag8.653 mouse myeloma cells was performed according to the procedures of de St. Groth and Scheidegger. Aliquots of 50 μ l hybridomas were transferred to each well of five 96-well tissue culture plates (Flow Labs, Costa Mesa, Calif.) already containing 200 μ l HAT medium (10⁻⁴ mol/L hypoxanthine, 1.6 \times 10⁻⁵ mol/L thymidine, and 4 \times 10⁻⁷ aminopterin) and 3600 mouse peritoneal macrophages. When hybrids developed, media were screened with a dot blot assay as described below. Positive cultures were cloned by the limiting dilution method in 96-well culture plates. After 2 to 4 weeks of growth, culture media were again screened and the positive hybrids grown up and recloned.

Screening for CA 125 antibodies. Culture media were screened with a nitrocellulose dot blot procedure. Ascites fluid with a CA 125 concentration of 22,000 U/ml was diluted 1:20 in phosphate-buffered saline solution; 100 µl was dot blotted to nitrocellulose with a dot blot apparatus (Schleicher & Schuell, Inc., Keene, N.H.). Control ascites with <20 U/ml CA 125 diluted 1:20 was also blotted to nitrocellulose. All blots were rinsed twice with phosphate-buffered saline solution and placed in blotto (5% dry milk powder in phosphatebuffered saline solution) overnight. Individual dots were cut from the blot, and 100 µl of each hybrid culture medium was added to tubes containing one control dot (low CA 125) and one test dot (high CA 125). Dots were incubated for 3 hours at room temperature, at which time 0.5 ml of blotto was added to each tube and incubated for a further 10 minutes. All tubes were then aspirated, and the dots were washed twice with 1 ml phosphate-buffered saline solution. Tubes were then incubated with a second antibody, goat/antimouse peroxidase (Biorad Corp., Richmond, Calif.) diluted 1:250; 250 µl was added to each tube. After the second antibody was incubated for 1 hour at room temperature, the tubes were aspirated; the dots were washed twice with phosphate-buffered saline solution and then exposed to horseradish peroxidase color developer as described by Biorad Corp. instructions.

Productive cultures were transferred to 1 ml culture dishes and grown out with at least two changes of media; they were then screened with a dot blot assay similar to that described above, except purified CA 125 was used as the positive test dot. Normal human serum (diluted 1:20) was used as the negative control. Screening also was carried out by saturating OC 125 beads (Centocor, Malvern, Pa.) with CA 125 antigen by exposing the beads to 1 ml of ascites fluid containing CA 125 22,000 U/ml overnight at room temperature. The beads were then washed twice with 5 ml phosphate-buffered saline solution and further incubated for 3 hours at room temperature with rabbit antimouse immunoglobulin G to saturate any OC 125 antibody not occupied by CA 125 antigen. After washing, beads were

exposed to culture media for 3 hours at room temperature. The beads were washed twice with phosphate-buffered saline solution and exposed to peroxidase-coupled antibody (goat antimouse peroxidase) and incubated for 1 hour at room temperature. Beads were aspirated and exposed to peroxidase substrate for color development. Control culture medium was used to determine background levels of staining.

Competition of new antibodies for OC 125 epitope. Culture media from positive hybrids along with control culture media (from nonproductive wells) were incubated with iodine 125-OC 125 antibody in a binding assay for CA 125 antigen. OC 125 beads (Centocor kit) were exposed to 0.4 ml ascites fluid (22,000 U/ml CA 125) overnight at room temperature. Beads were washed twice with 5 ml phosphate-buffered saline solution and exposed to 100 µl of 125 I-OC 125 antibody in the presence of 100 µl of culture media from each of the productive hybrids and media from two nonproductive hybrids for a further 18 hours at room temperature. Beads were washed and counted according to kit instructions. Similar competition studies were carried out by preloading individual OC 125 beads with CA 125 antigen obtained from normal human serum, tumor serum, ascites fluid, breast milk, and amniotic fluid that contained high levels of CA 125. CA 125 beads were then exposed individually to M-2 or M-11 or to control culture media in the presence of 125 I-OC 125 as described above.

Groups of six BALB/c mice were preconditioned with peritoneal injections of 0.5 ml Pristane (Aldrich Chemical, Milwaukee) 14 days before injection with 10⁶ hybridoma cells. Ascites fluid was harvested approximately 7 to 9 days after hybridoma injection. Fluid was centrifuged to remove cells, and the supernatant containing monoclonal antibody was stored frozen (-70° C) until used.

Immunoprecipitation. Aliquots (500 μl) of normal human serum, amniotic fluid, and CA 125-positive ascites fluid were incubated with 100 μl of 1:100 dilution

of each of the test monoclonal antibodies and ascites from one control mouse overnight at 4° C. Two hundred µl of rabbit antimouse immunoglobulin G Agarose beads (Biorad Corp.) diluted 1:2 were added to each tube and incubated for 4 hours at room temperature with agitation. After centrifugation, the beads were aspirated and washed twice with 1 ml buffer (5% albumin in phosphate-buffered saline solution containing 0.1% azide) and twice with 1 ml of bis-Tris buffer (20 mmol/L bis-Tris propane 7.2). The beads were then exposed to 50 µl of 2× electrophoresis sample buffer²⁵ for 3 minutes at 100° C. The beads were cooled, then pelleted at 2000 revolutions/min for 10 minutes, and the supernatant was removed for sodium dodecyl sulfate—polyacrylamide gel electrophoresis.

Electrophoresis/transblotting. Sodium dodecyl sulfate—polyacrylamide gel electrophoresis electrophoresis was carried out on 4% to 20% gradient polyacrylamide gels, according to Laemmli,25 for 4 hours at 30 mA. After electrophoresis, the gels were soaked in Trisglycine buffer (24 mmol/L Tris hydrochloride, 192 mmol/L glycine, pH 8.3) and transblotted to an Immobilon PVDF filter (Amicon Corp.) with the Tris-glycine buffer with 15% (vol/vol) methanol overnight at 30 V.

Western blotting. Immobilon filters were incubated for 30 minutes at room temperature with blotto, followed by two washes in phosphate-buffered saline solution for 10 minutes each. Blots are then exposed either to mouse ascites monoclonal antibody at a dilution of 1:100 in phosphate-buffered saline solution or to OC 125—125I antibody (Centocor kit) at a 1:10 dilution at 4° C overnight. The filters were then washed once with blotto for 10 minutes, followed by two washes in phosphate-buffered saline solution. The blot was then exposed either to x-ray film overnight if 125I—OC 125 was used or to peroxidase-coupled second antibody, (goat antimouse peroxidase) at 1:250 dilution (Biorad Corp.) if mouse monoclonal ascites was used. Second antibody incubation was carried out at room temper-

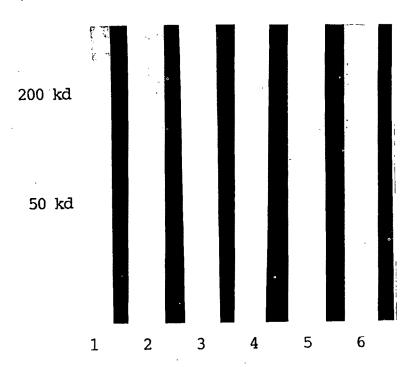

Fig. 1. Western blot of CA 125-rich (22,000 U/ml) ascites fluid. Lanes 1 to 6 were probed with monoclonal antibodies M2, 11, M6, M1, M3, and control mouse ascites, respectively.

Table III. Competition for CA 125 epitope

	¹²⁵ I-OC 125 bound (%)

M2 Antibody	0.9	1.3	2.6	1.8	2.3

ature for 1 hour; filters were washed with blotto and phosphate-buffered saline solution as described above. Blots were developed with 4-chloro-I-naphthol color substrate (Biorad Corp.) as described above.

Immunohistochemistry. For immunohistochemical studies, sections (5 µm) of formalin-fixed, paraffinembedded tissues were deparaffinized and rehydrated through serial alcohol baths to water. The hydrated sections were treated with 3% hydrogen peroxide for 10 minutes to block endogenous peroxidase activity, followed by exposure to normal goat serum to reduce nonspecific background staining. Primary monoclonal antibody, diluted 1:100 in phosphate-buffered saline solution, was added to sections at room temperature and incubated for 30 minutes. Linking antibody and labeling antibody were applied to tissue sections, according to kit instructions supplied by Dako (Santa Barbara, Calif.) second-antibody kits. The substrate used for localization of antibody binding was 3-amino-9ethyl-carbazole (2%). Counterstaining was achieved with Mayer's hematoxylin. Negative control slides were

prepared in identical fashion with either normal mouse serum or mouse ascites in place of the primary antibody.

Results

The initial screening process of hybrid media with low CA 125 and high CA 125 dot blot analysis yielded 24 wells with a positive dot blot test. A dot was scored positive when staining was present on the test dot (+CA 125) and negative on the control dot (low CA 125). Rescreening of these 24 expanded hybrids with both purified CA 125 and normal human serum (low CA 125) by dot blot analysis and by OC 125 bead binding yielded 12 positive hybrids of CA 125 antibody-producing hybridomas (Table I). Both dot blots and beads were graded visually on a scale of 1 to 4 for color development. Further analysis of the 12 media from the positive wells by competition analysis with 125 I-OC 125 binding to the CA 125 antigen in competition with the individual antibodies present in the positive wells indicated that media from one well described here as M2

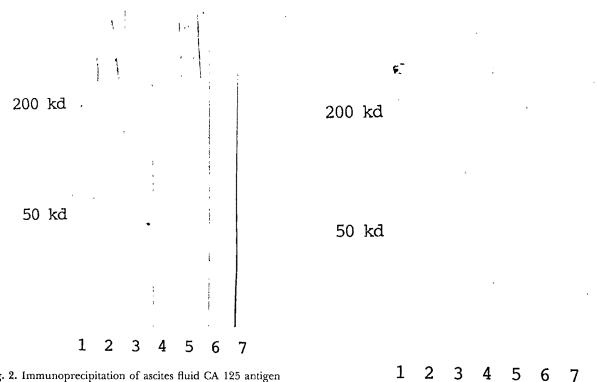

Fig. 2. Immunoprecipitation of ascites fluid CA 125 antigen with newly developed monoclonal antibodies, followed by Western blotting and probing of individual lanes with homologous monoclonal antibody. Lanes 1 to 7 were individually probed with M1, M2, M3, M6, M11, M12, and control mouse ascites.

Fig. 3. Immunoprecipitation of ascites fluid CA 125 followed by Western blotting of precipitates, as described in Fig. 2, but individual lanes were probed with 125I-OC 125.

(Table II) effectively competed for a site similar to, or the same as, the OC 125 antibody. Control media or other positive media did not compete with 125 I-OC 125 binding to CA 125. After cloning, six hybrids continued to recognize CA 125. These cloned hybridomas were then used to produce ascites in Pristane-treated BALB/c mice. When M2 antibody was produced as ascites, it competed effectively with 125 I-OC 125 whether the source of CA 125 antigen was serum or ascites obtained from tumor patients or human serum, normal amniotic fluid, or breast milk (Table III).

Western blot screening of these monoclonal antibodies indicated that antibodies designated M2 and M11 recognized high-molecular-weight antigenic determinants (>200 kd) as indicated in lanes 1 and 2 (Fig. 1). Electrophoresis patterns of nonpurified CA 125 often give a smudged appearance after blotting. This is because of the association of the antigen with mucinlike high-molecular-weight glycoproteins (lanes 1 and 2, Fig. 1). Low-intensity binding by M6 (lane 3, Fig. 1) also was detectable on the original blot but was not readily visible in Fig. 1. Immunoprecipitation of tumor ascites CA 125 antigen was carried out with monoclonal antibodies derived from the six productive hybridomas and control mouse ascites. This was followed by electrophoresis, blotting, and probing with homologous antibodies indicating that monoclonal antibodies M2 and M11 (lanes 2 and 5, respectively, Fig. 2) recognize multiple high-molecular-weight antigenic species >200 kd. Monoclonal antibody M1 recognizes a 68 kd subunit (lane 1) distinct and separate from antibodies M2 and M11. Immunoprecipitation, electrophoresis, and blotting of a second set of these antibodies probed with the heterologous 125 I-OC 125 antibody indicates that OC 125 recognizes at least one of the molecular species precipitated by both M2 and M11 (lanes 2 and 5, respectively, Fig. 3). No other immunoprecipitate, including the 68 kd recognized by M1, was readily detected with OC 125. Immunoprecipitate of antigen from CA 125-rich sources such as ascites (22,000 U/ml) and amniotic fluid (2000 U/ml) and CA 125deficient sources such as normal human serum (CA 125 <10 U/ml) further demonstrates recognition by M2 and M11 of CA 125 (Fig. 4, A and B). Immunoprecipitates of ascites from nonimmunized mice are shown in Fig. 4, C. Lane 1 in each panel, which is ascites immunoprecipitate (rich in CA 125), clearly indicates that M2 (A) recognizes high-molecular-weight antigen from this source. M2 shows only faint bands for CA 125 antigen derived from the less abundant amniotic fluid source of CA 125 (lane 2, B). Essentially no antigen can be detected in immunoprecipitates from normal hu-

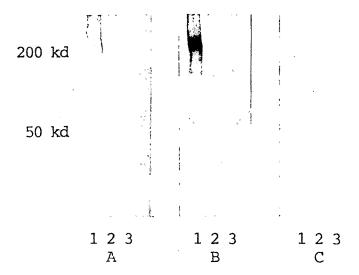

Fig. 4. Immunoprecipitation of CA 125 from ascites fluid, amniotic fluid, and normal human serum (lanes 1 to 3) with monoclonal antibody M2 (A), M11 (B), and control ascites (C) followed by Western blotting and probing with homologous antibodies.

man serum (lane 3, *B*). Similarly, probing with M11 confirms that ascites provides a rich source of CA 125 and amniotic fluid, a poorer source. M11 did not bind immunoprecipitates of normal human serum (lanes 1 to 3, *B*). Control ascites contained no antibody capable of recognizing CA 125 from all sources of the antigen (*C*). Bands at 50 kd and approximately 30 kd represent mouse immunoglobulin G heavy and light chain recognized by the goat anti-mouse second antibody.

Evaluation of antibodies by immunohistochemical localization in known CA 125-positive tissues further indicates recognition by these antibodies of antigen localized within cells also recognized by the monoclonal antibody OC 125 (Fig. 5). OC 125 has previously been shown to stain distinctly the single epithelial cellular layer of the amniotic membrane. Comparative staining of monoclonal antibodies M2 (A), M11 (B), M1 (C), and OC 125 (D) along with mouse ascites control (E) demonstrates the specific localization of these antibodies to the amnion. Distribution of antibody within the amniotic epithelial cells is more evident with M2 (A) and M1 (C), whereas extracellular or glycocalyx localization of the antibodies is evident with M11 (B) and OC 125 (D).

Comment

Expression of CA 125 during fetal development on the epithelium of müllerian duct derivatives (for example, cervix, corpus, and fallopian tube) and on derivatives of coelomic epithelium (peritoneum, pleura, and pericardium) has been documented by Kabawat et al.³ Expression of the antigen on the developmental sites is maintained through adulthood, resulting in the presence of CA 125 in all non-tumor-bearing adults.

More recently, we have described abundant levels of CA 125 in amniotic fluid, and it is now clear that both the amnion and the fetal periderm are major sources of CA 125 during gestation.17, 18 It is therefore somewhat surprising that CA 125 is a useful marker for ovarian cancer, in light of the presence in abundance of the antigen in normal tissues. Antigen produced by normal tissues may account for the low but detectable levels of CA 125 that are measurable in both men and women. The large quantities of CA 125 present in the endometrium and cervix are normally secreted to the outside without access to the circulation. In special cases, for example, in patients with endometriosis, during menses, and during embryo implantation and early gestation, CA 125 gains access to the circulation through disruption of the endothelium and results in elevated CA 125 levels. 13-15 In patients with ovarian carcinoma, access to the circulation in measurable amounts occurs relatively late in the disease process; most patients with ovarian carcinoma are diagnosed in the advanced stages (e.g., stages III and IV) when elevated levels of CA 125 might be expected. 1.4.5 As previously mentioned, at second-look laparotomy, when foci of disease are <2 cm, the CA 125 level often is not elevated or not detected in the blood.9

It is apparent that new monoclonal antibodies that have higher affinity for the CA 125 glycoprotein (1) would provide the basis for an assay system that could detect relatively low levels of serum CA 125, (2) would discriminate between CA 125 antigen synthesized by ovarian carcinoma cells and normal tissues and so would have significant importance to patient care, (3) are capable of recognizing the cell surface of tumor cells and would provide a means of radioisotope im-

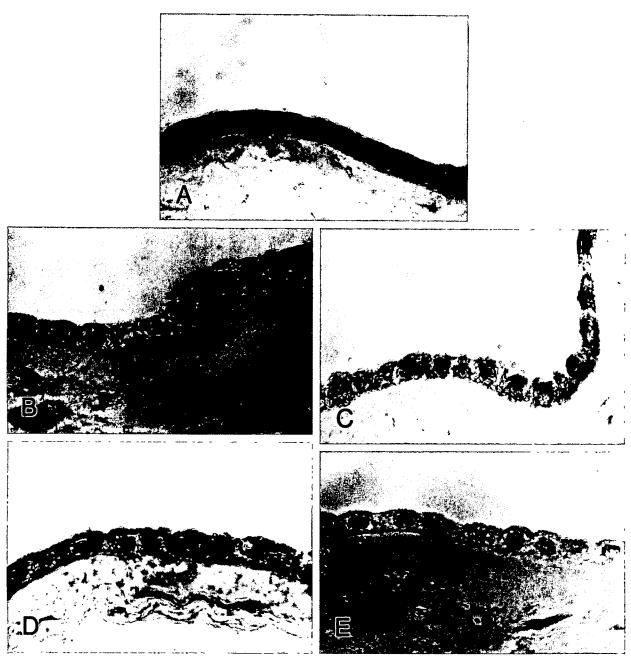

Fig. 5. Immunolocalization of CA 125 antigen in amnion epithelium with M2 (A), M11 (B), M1 (C), OC 125 (D), and control mouse ascites (E). (Original magnification ×100.)

aging or as delivery systems for therapeutic agents and would enhance diagnosis and therapy, and (4) are able to recognize individual domains of the CA 125 molecule and would simplify mapping of the biologically active sites of the CA 125 molecule, providing insight into the normal function of CA 125. Our initial efforts have yielded new monoclonal antibodies, providing the basis for initiating such studies.

These antibodies include one (M2) that competes with OC 125 for binding to the CA 125 antigen. It recognizes large-molecular-weight subspecies of CA

125 similar to OC 125 and similar to the purified subspecies described by Davis et al.22 M11, a second monoclonal antibody, does not compete for the OC 125 binding site but does immunoprecipitate multiple CA 125 subspecies similar to M2. OC 125 recognizes a major subspecies of those precipitated by M2 and M11. Even though these two antibodies recognize similar CA 125 subspecies, immunolocalization of antigen that uses the amnion as a test system indicates a significant difference in cellular distribution of determinants recognized by these two antibodies. M2 is almost entirely localized within the amniotic epithelium, relatively evenly distributed throughout the cytoplasm. In contrast, M11 is almost exclusively localized to the extracellular glycocalyx matrix and appears to recognize poorly the intracellular antigen recognized by M2. Antibody recognition of antigen localized to the extracellular matrix is of interest because drug delivery or imaging systems can best be directed with antibodies recognizing the cell surface. On the other hand, cytoplasmic recognition of the antigen is most important for antibodies that might be used to screen complementary deoxyribonucleic acid libraries where antibodies that recognize protein epitopes with no posttranslational modifications are desired. Both the M1 antibody, which recognizes a unique 68 kd subunit of the CA 125 molecule, and the M2 antibody, which recognizes high-molecular-weight subunits of the CA 125 molecule, are localized in the cytoplasm. The availability of these new antibodies will improve our ability to (1) further define the CA 125 molecule and its constituent domains, (2) screen and potentially identify the CA 125 gene(s), (3) allow more direct immunopurification of the CA 125 antigen, (4) further enhance our ability to detect and specify tumor CA 125 antigen in patient sera, and (5) direct chemotoxic agents or imaging isotopes to the surface of peritoneal tumor cells.

Specific binding sites for insulin and insulin-like growth factor I in human endometrial cancer

Manubai Nagamani, MD, Charles A. Stuart, MD, Patricia A. Dunhardt, BA, and Mark G. Doherty, MD

Galveston, Texas

Insulin and insulin-like growth factor I are known to be mitogenic and therefore may play a role in the development of endometrial cancer. We undertook this study to investigate whether human endometrial cancer tissue has receptors for these substances. Endometrial cancer tissue samples were obtained at hysterectomy from 10 women with endometrial cancer, and control endometrial tissue was collected from normal cycling women undergoing hysterectomy for nonendocrine problems. Binding studies with jodine 125-insulin and [125] insulin-like growth factor I revealed the presence of specific binding sites for insulin and insulin-like growth factor I in both normal endometrium and endometrial cancer tissue. The percent binding of [1251]insulin in the endometrial cancer tissue (mean \pm SE 2.4% \pm 0.5%/100 μg protein) was not significantly different from that in normal endometrium (3.5% \pm 1%/100 μg protein). On the contrary, the percent total binding of [125]insulin-like growth factor I in the endometrial cancer (5.3% ± 1.5%/100 μg protein) was significantly (p < 0.04) higher than that observed in normal endometrium (2.1% \pm 0.4%/100 μg protein). There was a significant positive correlation between the histologic grade of the tumor and the insulin-like growth factor I binding (r = 0.865, $\rho < 0.02$). The affinity constants for the high-affinity receptors were similar in the normal and neoplastic endometrium. These results indicate that insulin and insulin-like growth factor I may play a role in the growth and development of endometrial cancer. (AM J OBSTET GYNECOL 1991;165:1865-71.)

Key words: Insulin receptor, insulin-like growth factor I receptors, endometrial cancer

Postmenopausal women with endometrial cancer have increased serum insulin levels, and their insulin response to glucose ingestion is increased.1 Insulin and insulin-like growth factors (IGF) (specificially IGF-I) have been shown to be mitogenic, and most types of tumor cells are dependent on insulin for their proliferation.24 Insulin and IGF-I receptors are closely related to tyrosine kinase family of oncogenes.⁵ Insulin and IGF-I therefore may play a role in the growth and development of endometrial cancer. IGF-I messenger ribonucleic acid has been demonstrated in the rat uterus, and estrogens increase IGF-I messenger ribonucleic acid synthesis.6,7 It is possible that IGF-I of uterine or extrauterine origin plays a role in the growth and proliferation of the endometrial cancer cells in an endocrine, autocrine, or paracrine fashion.

We undertook this study to investigate (1) whether human endometrial cancer has binding sites for insulin

From the Departments of Obstetrics and Gynecology and Medicine, The University of Texas Medical Branch.

Supported by National Institutes of Health grants Nos. CA45181 and DK33749 and National Institutes of Health General Clinical Research Center grant No. M01-RR00073.

Presented at the Thirty-eighth Annual Meeting of the Society for Gynecologic Investigation, San Antonio, Texas, March 20-23, 1991. Reprint requests: Manubai Nagamani, MD, Department of Obstetrics and Gynecology, The University of Texas Medical Branch, Galveston, TX 77550.

6/6/33229

and IGF-I, (2) if these sites are present, whether the concentrations of these receptors are increased in endometrial cancer tissue compared with normal endometrium, (3) whether the concentrations of these receptors correlate with the histologic grade of the tumor, and (4) whether there is an increase in serum IGF-I levels in women with endometrial cancer.

Material and methods

After the study was approved by the institutional review board, endometrial cancer tissue samples were obtained at hysterectomy from 10 patients with endometrial cancer. Normal endometrial tissue was obtained from women undergoing hysterectomy (in the proliferative phase of the cycle) for nonendocrine problems (cervical dysplasia, pelvic pain, pelvic relaxation). The tissue was washed in ice-cold buffer to remove any blood, quickly frozen in liquid nitrogen, and stored at -72° C until use. The day before hysterectomy fasting blood samples were obtained from all patients with cancer for measurement of insulin, glucose, and IGF-I levels. Nine of the 10 patients with cancer were obese, weighing >20% above their ideal body weights. Ideal body weights were determined from the Metropolitan Life Insurance Company tables. The ages of the patients varied from 40 to 70 years. Two of the patients were premenopausal and had a history of oligomenorrhea since menarche. The rest of the cancer patients

Table I. Clinical data for patients with endometrial cancer

were 1 to 20 years postmenopausal and gave a history of regular menstrual cycles before the onset of menopause. Fasting insulin levels were increased in all the patients, but fasting glucose levels were normal. Serum IGF-I levels were in the normal range. Clinical data on the endometrial cancer patients are presented in Table I.

Binding studies. To prepare endometrial membranes, we used, with minor modification, a technique developed for cartilage plasma membranes.⁸ Endometrial tissue (400 to 500 mg) was homogenized in 15 ml 0.01 mol/L imidazole, 0.25 mol/L sucrose, and 0.005 mol/L ethylenediaminetetraacetic acid, pH 7.5 (ISE buffer), at 0° C for 60 seconds at half speed with a Polytron device (Brinkmann Instruments, Westbury, N.Y.). The homogenate was centrifuged at 1000g for 15 minutes to remove nuclei, most mitochondria, and tissue fragments. The resulting supernatant was centrifuged at 35,000g for 60 minutes to provide a final pellet that was resuspended in 0.001 mol/L imidazole, pH 7.5.

Human insulin was the generous gift of Lilly Research Laboratories, Indianapolis. IGF-I and IGF-II were purchased from Bachem, Inc. (Torrance, Calif.). Insulin, IGF-I, and IGF-II were radiolabeled with iodine-125 with minor modifications of the dilute chloramine-T method of Freychet et al.9 Insulin and IGF-I binding studies were performed in 0.1 mol/L N-[2-hydroxyethyl]piperazine-N'-[2-ethanesulfonic acid], 0.120 mol/L sodium chloride, 0.0012 mol/L magnesium sulfate, 0.001 mol/L ethylenediametetraacetic acid, 0.01 mol/L glucose, 0.015 mol/L sodium acetate, and 1% bovine serum albumin, pH 8.0, as previously described.10 Studies designed for Scatchard analysis of binding parameters consisted of eight different concentrations of insulin performed in triplicate. The concentrations of [125] insulin was approximately 0.05×10^{-9} mol/L, unlabeled porcine insulin was

added to achieve concentrations of 0, 0.2, 0.5, 1, 2, 10, 20, 100, and 1000×10^{-9} mol/L, and the membrane protein concentration was ≤1 mg/ml. For IGF-I binding studies unlabeled IGF-I and [125I]IGF-I were used in similar concentrations. The mixtures were incubated at 4° C for 15 to 18 hours, and the membranes were sedimented by centrifugation at 18,000g for 15 minutes and washed once in binding buffer. The results are expressed as the percentage of total radioactivity bound per 100 µg membrane protein. Protein was quantitated by the method of Lowry et al.11 Nonspecific binding was determined in the presence of at least 200fold molar excess of unlabeled insulin and IGF-I, respectively. Analysis of binding data was performed with a computer program designed to provide the best fit of a two-receptor model to the Scatchard plot. The program performs an iterative curve-stripping procedure in which a curvilinear Scatchard plot is stepwise recalculated, subtracting an increasing number of counts as a result of low-affinity specific binding until the optimal high-affinity straight line is achieved.10

Specificity studies. To evaluate the specificity of IGF-I binding, endometrial membranes were incubated in the presence of a constant amount (1×10^5 cpm) of [125 I]IGF-I, with or without increasing concentrations of unlabeled IGF-II (I to 100 nmol/L), IGF-I, or insulin (I to 1000 nmol/L). To evaluate the specificity of insulin binding, the membranes were incubated in the presence of a constant amount (1×10^5 cpm) of [125 I]insulin with or without increasing concentrations of unlabeled insulin (I to 1000 nmol/L), or IGF-II.

Affinity labeling and gel electrophoresis. Specific labeling and cross-linking with disuccinimidyl suberate and electrophoresis were performed essentially as previously described for liver membranes, 2 except separating gels were 5% polyacrylamide.

Serum IGF-I levels were measured with a kit pur-

^{*}Normal range 36 to 107 pmol/L.

[†]Normal range 36 to 233 ng/ml.

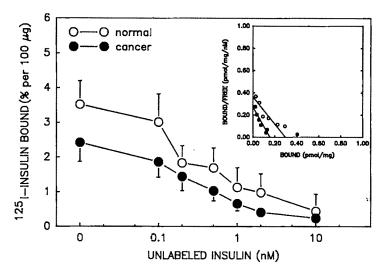

Fig. 1. Specific insulin binding (mean \pm SE) to endometrial membranes from human endometrial cancer (n = 10) and normal endometrium (n = 10). Inset, Scatchard plot of same data.

chased from Nichols Institute (San Juan Capistrano, Calif.) after extraction with acid ethanol to remove binding proteins. Insulin levels were measured by a previously described radioimmunoassay procedure. Independent Student t test was used to compare differences in specific binding between control endometrium and endometrial cancer. A p value of <0.05 was considered significant. Spearman's rank correlation was calculated between the histologic grade of the tumor and the specific binding of IGF-I and insulin to endometrial membranes.

Results

Insulin-binding studies. Specific binding sites for insulin were present in both the normal and cancerous endometrial tissue. The percent total binding of [125] Insulin in the endometrial cancer tissue (mean \pm SE 2.4% \pm 0.5%/100 µg protein, range 0.9% to 9.0%/100 µg protein) was not significantly different from that in the normal endometrium (mean ± SE $3.5\% \pm 1\%/100 \,\mu g$ protein, range 0.5% to 5.3%/100 μg protein). Fig. 1 shows the competition curves for binding of [125] insulin to endometrial membranes from normal endometrium and endometrial cancer tissue. The inset of Fig. 1 shows the mean data for Scatchard plots. The affinity constants for these high-affinity receptors were similar in the normal $(4.0 \pm 1.5 \times 10^9)$ mol/L) and neoplastic (3.0 \pm 0.6 \times 10° mol/L) endometrium. The mean receptor concentration in the neoplastic endometrial tissue (0.11 ± 0.02 pmol/mg protein) was not significantly different from that in the normal endometrial tissue (0.33 ± 0.12 pmol/mg protein). There was no correlation between the stage or grade of the tumor and the insulin-binding activity.

Specificity. Fig. 2 shows the competition curves for binding of [125I]insulin to endometrial membranes pre-

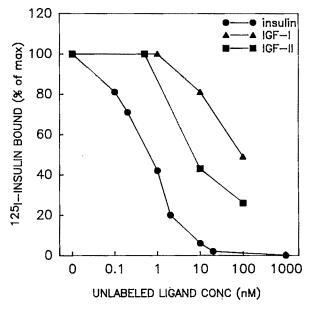

Fig. 2. Specificity of insulin binding to endometrial membranes. Each data point represents mean of triplicate determinations expressed as percent of counts bound in absence of unlabeled ligand.

pared from normal and neoplastic endometrium in the absence and presence of varying concentrations of insulin, IGF-I, and IGF-II. Increasing concentrations of unlabeled insulin resulted in dose-dependent displacement of the specific insulin binding. IGF-II was approximately tenfold and IGF-II 100-fold less potent in competing for binding. Results of these specificity studies indicate that the endometrial membranes have specific receptors for insulin.

IGF-I-binding studies. Specific binding sites for IGF-I were present in both normal and neoplastic endometrial tissue. Fig. 3 shows the competition curves

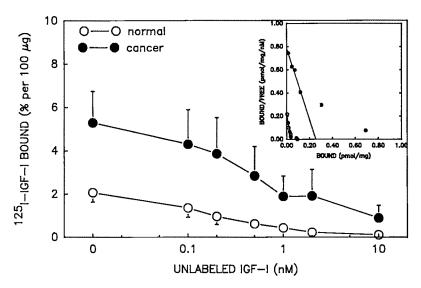

Fig. 3. Specific IGF-I binding (mean \pm SE) to endometrial membranes from human endometrial cancer (n = 10) and normal endometrium (n = 10). Inset, Scatchard plot of same data.

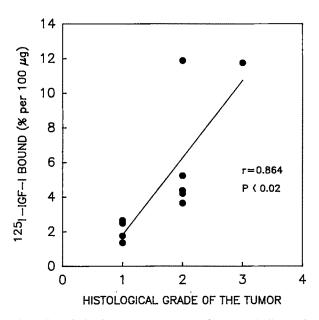

Fig. 4. Correlation between percent specific IGF-I binding and histologic grade of tumor.

for the binding of [125 I]IGF-I to endometrial membranes from normal endometrium and endometrial cancer tissue. The inset of Fig. 3 shows the mean data for Scatchard plots. The percent of total binding of IGF-I in the normal endometrial tissue was $2.1\% \pm 0.4\%/100~\mu g$ protein (range 0.5% to $4.2\%/100~\mu g$ protein). The percent of total binding of IGF-I in the endometrial cancer tissue ($5.3\% \pm 1.5\%/100~\mu g$ protein, range 1.3% to $11.9\%/100~\mu g$ protein) was significantly higher (p < 0.04) than that in normal

endometrium. The affinity constants for these high-affinity receptors were similar (8.6 \pm 1.2 \times 10° mol/L, normal endometrium; 8.1 \pm 1.8 \times 10° mol/L, endometrial cancer tissue). The mean receptor concentration was 0.05 \pm 0.03 pmol/mg membrane protein in the normal endometrium and 0.26 \pm 0.1 pmol/mg protein in the neoplastic endometrium. There was a significant correlation between IGF-I binding in the endometrial cancer tissue and the histologic grade of the tumor (r = 0.864, p < 0.02) (Fig. 4).

Specificity. The results of specificity studies on IGF-I binding are shown in Fig. 5. Increasing concentrations of unlabeled IGF-I resulted in dose-dependent displacement of specific IGF-I binding. IGF-II was five-fold less potent in its ability to compete for [125I]IGF-I binding. Insulin was able to compete for binding at higher concentrations and produced 50% displacement at 300 nmol/L concentration.

Autoradiography of dried polyacrylamide gels demonstrated specific labeling of bands of 130,000 and >300,000 molecular weight for radiolabeled insulin and IGF-I. Unlabeled insulin prevented 61% of the labeling with [125]IGF-I, whereas unlabeled IGF-I prevented 88% of the labeling with [125]insulin (Fig. 6). The 130,000-molecular-weight band is believed to be the binding subunit of type I IGF receptor. The specifically labeled larger-molecular-weight material probably represents subunits that are cross-linked together by disuccinimidyl suberate. Two bands of specific insulin binding with apparent molecular weights of 130,000 and >300,000 are similar to those observed for insulin receptors in rat liver and human placental membranes. The specific insulin receptors in rat liver and human placental membranes.

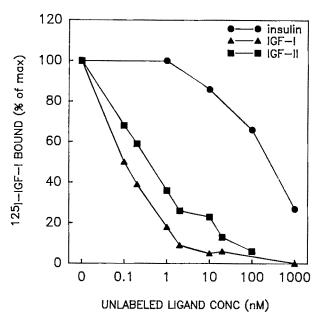

Fig. 5. Specificity of IGF-I binding to endometrial membranes. Each data point represents mean of triplicate determinations expressed as percent of counts bound in absence of unlabeled ligand.

Comment

The association of obesity and endometrial cancer is well known.14 Obesity is associated with insulin resistance and hyperinsulinemia. We have previously reported that insulin levels are increased in postmenopausal women with endometrial cancer.1 Premenopausal women with polycystic ovarian disease have hyperinsulinemia; these women are at increased risk for development of endometrial cancer at an earlier age.15 The significance of this association of hyperinsulinemia and endometrial cancer, however, is not well understood. Prolonged administration of pharmacologic doses of insulin was found to exert a carcinogenic effect in mice.16 Mammary carcinomas induced in rats were found to be dependent on insulin, and most of these tumors regressed in size or grew slower when the animals were deprived of insulin with administration of alloxan.17 Insulin stimulates growth of numerous cell lines in vitro, including breast cancer cells.18 Because the results of our study show that the neoplastic endometrial tissue contains specific high-affinity binding sites for insulin, insulin might play a role in the growth or development of endometrial cancer as well. Surrey et al. 19 observed that insulin and IGF-I stimulate proliferation of endometrial stromal cells in culture. There has been only one previous study on insulin binding in the human endometrium. Sheets et al.20 reported the presence of specific binding sites for insulin in the normal human endometrial tissue. Our results in normal endometrium are similar to those reported in this pre-

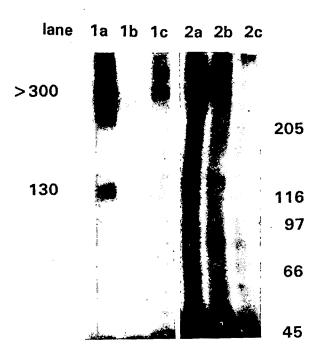

Fig. 6. Autoradiograph of 3-(trimethylsilyl)-l-propane-sulfonic acid and cross-linked affinity labeling of insulin and IGF-I receptors in endometrial membranes. Shown here is autoradiograph of endometrial membranes labeled with [125I]insulin and IGF-I in presence or absence of unlabeled ligands. Samples were reduced with mercaptoethanol and electrophoresed through polyacrylamide gels as described in Material and methods. Lane 1a contains radiolabeled insulin that is cross-linked in absence of unlabeled ligand, whereas lane 1b sample was bound in presence of 100 nmol/L unlabeled insulin and lane 1c shows labeling in presence of 100 nmol/L unlabeled IGF-I. Lane 2a shows labeling with [1251]IGF-I in absence of unlabeled ligand. Lanes 2b and 2c show labeling with [125I]IGF-I in presence of 100 nmol/L unlabeled insulin or IGF-I, respectively. Specifically labeled large-molecularweight material probably represents subunits that are crosslinked together by disuccinimidyl suberate. There is no evidence of IGF-II receptor or specifically labeled binding proteins.

vious study. We have shown for the first time that human endometrial cancer has specific binding sites for insulin. The mean insulin receptor concentration in the endometrial cancer was slightly lower than that in the normal endometrium, but the difference was not statistically significant. The decrease in insulin receptor concentration could be due to down-regulation that is a secondary effect of the elevated peripheral insulin levels. Since only a small percentage of insulin receptors are occupied at insulin concentrations that have maximal biologic effects, a decrease in receptor binding would not be expected to change the maximal effect of insulin.21 Insulin in high concentrations binds to IGF-I receptors.²² The effect of insulin therefore might be mediated either through its own receptor or by cross1870 Nagamani et al.

December 1991

Am J Obstet Gynecol

over stimulation through IGF-I receptor. Our specificity data do support possible crossover action.

The other possible role of insulin in the pathogenesis of endometrial cancer is to increase the aromatization of androgens in the endometrial tissue. Tseng et al.²³ reported that the endometrium has the ability to convert androgens to estrogen by aromatization. Randolph et al.²⁴ observed that the aromatase activity in the human endometrial glands and stroma increased proportionately with increasing concentrations of insulin.²⁴ Hyperinsulinemia can therefore lead to an increase in estrogen production at the endometrial tissue level.

The human endometrial tissue has specific high-affinity binding sites for IGF-I; therefore IGF-I of intrauterine or extrauterine origin might play a role in the growth and proliferation of endometrial cancer cells. Because the peripheral IGF-I levels were not significantly different between patients with cancer and controls, IGF-I produced locally in the endometrial tissue may be acting in an autocrine or paracrine fashion. Breast cancer cells have been shown to secrete IGF-I, and 17β-estradiol stimulates IGF-I production by these cancer cells.²⁵ Endometrial cancer, like breast cancer, is an estrogen-dependent cancer. Studies by Murphy et al.^{6, 7} indicate that estrogen induces IGF-I expression in the rat uterus. Estrogen-induced proliferation of endometrial cells might be mediated through IGF-I.

The binding activity of IGF-I was significantly higher in the neoplastic endometrium than in normal endometrium. Lack of a difference in receptor affinity, as shown by the Scatchard plots, indicates that the increasing binding is primarily due to an increase in the number of receptors. The fact that there was a significant positive correlation between the histologic grade of the tumor and the IGF-I binding indicates that IGF-I may play a role in the proliferation of the tumor cells. Undifferentiated tumors, which have increased miototic activity, had an increased number of binding sites for IGF-I when compared with the number in the welldifferentiated tumors. Surrey et al.19 observed increased tritium-thymidine incorporation on addition of IGF-I to endometrial stromal cell cultures. The only previous report on IGF-I binding in endometrial cancer tissue is that of Talavera et al.26 Our results are similar to this previous report, and these authors also observed increased IGF-I binding in undifferentiated tumors. Rutanen et al.27 looked at the IGF-I receptor and IGF-I-binding protein concentrations in the normal human endometrium at different phases of the menstrual cycle. These authors observed that there is an increase in the number of IGF-I receptors and 34K IGF-I-binding protein in the late secretory phase endometrium and that the binding protein competes with membrane receptors for IGF-I binding. There was no binding protein present in the proliferative phase endometrium.27 In our study all the normal endometrial

tissue samples studied were in the proliferative phase of the cycle. Because 8 of the 10 cancer patients were postmenopausal and the two premenopausal patients had anovulatory cycles, there was probably no 34K IGF-binding protein present in the cancer tissue and all the IGF-I receptors were probably available for IGF-I action. However, this needs to be confirmed by further studies on IGF-binding proteins in endometrial cancer tissue.

In conclusion, results of our study indicate that endometrial cancer tissue has specific binding sites for both insulin and IGF-I. Because most of the women with endometrial cancer are obese and have hyperinsulinemia, insulin may play a role in the growth and development of this tumor. Since we did not find an increase in peripheral IGF-I levels in women with endometrial cancer, it is possible that IGF-I is produced locally in the tissue and acts in an autocrine or paracrine fashion.

Increased progesterone concentrations are necessary to suppress interleukin-2-activated human mononuclear cell cytotoxicity

Bruce B. Feinberg, MD, Nenita S. Tan, MD, Bernard Gonik, MD, Peter C. Brath, BS, and Scott W. Walsh, PhD

Houston, Texas

Fetal trophoblast is generally resistant to lysis by cytotoxic cells. Trophoblast progesterone and estrogens may act at the choriodecidual interface, where they are present in high concentrations to provide a local, paracrine immunosuppressive effect on cellular cytotoxicity. However, interleukin activation of these cytotoxic lymphocytes enhances their ability to lyse trophoblast. Recent evidence suggests that immunoactivation occurs in certain aberrant pregnancy conditions, including preeclampsia. Preeclamptic placentas produce more progesterone in vitro than do normal placentas. To study the potential association between progesterone production and immunoactivation, we evaluated the immunomodulatory effect of progesterone on cellular cytotoxicity. Comparisons were made with the use of both normal and interleukin-2—stimulated peripheral blood mononuclear cells as effector cells in a cytotoxicity assay. Progesterone suppressed cytotoxicity in a dose-dependent manner. Interleukin-2 augmented cellular cytotoxicity, and higher concentrations of progesterone were required to attenuate this response. An additive suppression of cytotoxicity was also observed when estrone, estradiol, estriol, and progesterone were combined. We speculate that the higher placental production of progesterone seen in preeclampsia may be a trophoblast compensatory response to immunoactivated maternal effector cells. (Am J Obstet Gynecol 1991;165:1872-6.)

Key words: Progesterone, interleukin-2, cytotoxicity, preeclampsia

Local regulation of immune events at the choriodecidual interface is essential to fetal survival. Cytotoxicity by mononuclear cells is a nonspecific, primary immunodefense system that is active against foreign cells. Fetal trophoblast, however, is generally resistant to lysis by cytotoxic cells in normal gestation. Trophoblast progesterone and estrogens are present in high concentrations at the choriodecidual interface² and may exert a local, paracrine immunosuppressive effect on maternal cellular cytotoxicity. A homeostatic balance may, therefore, exist between maternal cytotoxic cells and fetal trophoblast to allow for fetal survival.

Interleukin (IL) activation of cytotoxic lymphocytes,

however, enhances their ability to lyse trophoblast. 4.5 If a balance between maternal cytotoxic cell activity and trophoblast progesterone does exist, then a compensatory increase in placental progesterone production would be anticipated in the presence of an activated maternal immune response. Recent evidence suggests that immunoactivation occurs in certain aberrant pregnancy conditions, including preeclampsia. 6-9 An increased natural killer cell activity in patients with preeclampsia has also been observed.10 Interestingly, preeclamptic placentas produce more progesterone in vitro than do normal placentas.11 In this study we evaluated the effects of progesterone on cellular cytotoxicity with both normal and IL-2-activated lymphocytes. We hypothesized that progesterone suppresses cellular cytotoxicity and that in an immunoactivated state increased progesterone concentrations are required to achieve inhibition of cytotoxicity to levels comparable to that of the normal, unstimulated state.

Material and methods

Experimental design. In vitro cellular cytotoxicity was studied with mononuclear cells obtained from normal, nonpregnant female volunteers. Parallel experiments were performed to evaluate the immunomod-

ulatory effects of progesterone with both normal and IL-2-stimulated effector cells. To evaluate whether a combination of progesterone and estrogens could have a cumulative immunomodulatory effect, we combined estrone, estradiol, estriol, and progesterone at a 25 µM concentration each and examined this effect on cytotoxicity with IL-2-stimulated effector cells. The experimental protocol was approved by the institutional committee for the protection of human subjects.

Effector cells. Peripheral blood mononuclear cells from normal, nonpregnant female volunteers were used as effector cells. Approximately 20 ml of peripheral venous blood was obtained from each volunteer and processed within 1 hour of collection. Blood samples were sedimented with 10% (vol/vol) of 3% dextran (Sigma Chemical Co., St. Louis). The leukocyte-rich plasma was then subjected to Ficoll-Hypaque (Pharmacia Laboratories, Inc., Piscataway, N.J.) buoyantdensity centrifugation. The leukocyte layer was aspirated from the plasma-Ficoll interface. These cells were washed three times in Hanks' balanced salt solution (Grand Island Biological Co. [Gibco], Grand Island, N.Y.) and resuspended to a concentration of 3×10^6 cells per milliliter in minimum essential media (Hazelton Research Products, Denver, Pa.) supplemented with 10% inactivated fetal calf serum (Flow Laboratories, Inc., Rockville, Md.), penicillin (50 U/ml), streptomycin (50 µg/ml), and L-glutamine (200 mmol/L). The cell suspension was then divided into two aliquots. One served as a control, and the other was resuspended and preincubated for 2 hours in the supplemented minimum essential media described, to which was added 100 U/ml of recombinant IL-2 (R and D Systems, Minneapolis). Further dilutions of both effector cell suspensions were performed to prepare effector-to-target cell ratios of 60:1, 30:1, and 15:1. Effector cell viability was determined by means of trypan blue exclusion at the time of cell suspension preparation and also after the experiment.

Cytotoxicity assay. Totals of 100 µl of effector cells (either normal or IL-2 stimulated), 50 µl of target cells, and 50 µl of reagent (supplemented minimum essential medium for controls; progesterone alone or in combination with estrone, estradiol, and estriol for experimental groups) were added to each well in U-bottom, 96-well culture plates (Corning Glass Works, Corning, N.Y.). Steroids were obtained from Sigma. All samples were run in triplicate to reduce intraassay variability. Spontaneous chromium release from the target cells was measured in triplicate wells containing only target cells and supplemented minimum essential medium. The covered plates were incubated as described for 18 hours. The amount of chromium released from the target cells was used as a quantitative indicator of cellular cytotoxicity. This was determined by aspirating 100 µl from the top of each well without disturbing the pellet and transferring it to a glass tube. To each remaining pellet, 100 µl of 1 N sodium hydroxide was added to lyse the cells. This total remaining volume was aspirated into a separate glass tube. All samples were assayed for radioactivity in a γ-counter (model 5010, Packard Cobra, Downer's Grove, Ill.) for 1 minute. Chromium release was calculated as follows:

% 51 Cr Release =
$$\frac{2A}{A + B} \times 100$$

where A is the counts per minute in the top 100 ml of supernatant and B is the counts per minute in the remaining pellet. Cellular cytotoxicity was calculated as a percentage:

$$\frac{\%}{100}$$
 for Release [(targets + effectors) - (targets only)] $\times 100$

Statistical analysis. Statistical analysis was done by analysis of variance. Individual groups were compared with the Scheffé post hoc test. A probability of p < 0.05was chosen to represent statistical significance.

Results

Effector cell viability was confirmed at >98% with trypan blue exclusion both before and after the experiments. A rise in cytotoxicity corresponding to increasing the effector/target ratios in the control wells suggested that the experimental method was valid. To optimize cellular cytotoxic effects all experimental wells were then evaluated with an effector-to-target cell ratio of 60:1. The data shown represent the mean percent cytotoxicity ± SE.

Progesterone suppressed cytotoxicity of unstimulated effector cells in a dose-dependent manner: 16.9 ± 1.5 (control), 11.5 ± 1.7 (50 μ mol/L), $7.2 \pm$ 0.9 (100 μ mol/L), 6.4 \pm 1.3 (200 μ mol/L), and 0.7 ± 0.7 (400 µmol/L). The addition of IL-2 produced a marked increase in the baseline percent cytotoxicity: 16.9 ± 1.5 (control) and 53.5 ± 3.7 (IL-2) stimulated): these values represent a threefold augmentation of cytotoxic activity. Progesterone also inhibited cytotoxicity in the IL-2-stimulated group in a dose-dependent manner: 53.5 ± 3.7 (control), $39.6 \pm 5.0 \ (50 \ \mu mol/L), \ 23.0 \pm 3.6 \ (100 \ \mu mol/L),$ 10.7 ± 2.4 (200 μ mol/L), and 2.8 ± 1.7 (400 μ mol/L) (Fig. 1). The combination of progesterone, estrone, estradiol, and estriol, each at a concentration of 25 µmol/L produced an additive suppression of cytotox-

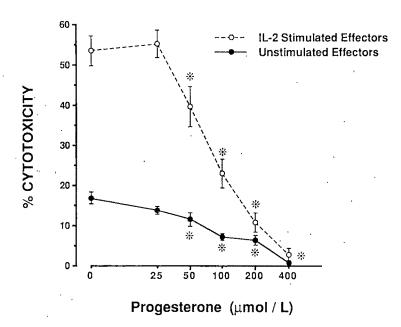

Fig. 1. Effects of progesterone on cellular cytotoxicity with unstimulated (n = 4) and IL-2-stimulated (n = 4) mononuclear effector cells. Results are expressed as mean percent cytotoxicity \pm SE. Effector/target cell ratio = 60:1. Asterisk, p < 0.05 (compared with wells not containing progesterone).

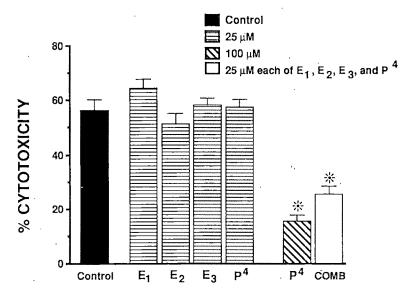

Fig. 2. Synergistic suppression of IL-2-stimulated cellular cytotoxicity resulting from combination (n=6) of estrone (E_1) , estradiol (E_2) , estriol (E_3) , and progesterone (P^4) each at 25 μ mol/L concentrations. Effector cells were IL-2 stimulated. Results are expressed as mean percent cytotoxicity \pm SE. Effector/target cell ratio = 60:1. Asterisk, p < 0.05 (compared with wells not containing progesterone).

icity in the IL-2-stimulated group: 56.5 ± 3.9 (control) and 25.6 ± 3.1 (combination). The degree of immunosuppression was equivalent to that of $100 \mu mol/L$ progesterone (Fig. 2).

To evaluate whether progesterone's ability to suppress cytotoxicity was due to stabilization of the target cell membranes, spontaneous chromium release was measured from target cells incubated with increasing concentrations of progesterone but in the absence of effector cells. No difference was observed in the spontaneous chromium release with increasing progesterone concentrations, suggesting that the observed progesterone effect was not due to target cell membrane stabilization.

Comment

Our results demonstrate that IL-2 stimulation of effector cells results in enhanced cytotoxicity against a susceptible target cell population. Progesterone suppressed cytotoxicity in a dose-dependent manner in both the unstimulated and IL-2-stimulated groups. Of particular interest is the finding that for any given percent cytotoxicity a greater progesterone concentration was required to suppress cytotoxic activity in the IL-2stimulated group as compared with the unstimulated effector cells. For example, roughly 17% cytotoxicity is the baseline value, in the absence of progesterone, for cytotoxicity in the unstimulated group. To achieve this same percent cytotoxicity in the IL-2-stimulated group, approximately 150 µmol/L progesterone was required. These findings supported our hypothesis that higher steroidal concentrations are necessary to suppress immunoactivated effector cells.

Since the normal hormonal milieu at the maternalfetal interface contains multiple steroids, we investigated the effect of a combination of steroids on cytotoxicity by immunoactivated cells. We have previously shown that the interaction of multiple sex steroids acts synergistically to inhibit cytotoxic cell activity with unstimulated effector cells.3 This concept was confirmed in this study by demonstrating an additive steroidal suppression of IL-2-stimulated mononuclear cell cytotoxicity.

During normal gestation fetal trophoblast are generally resistant to lysis by cytotoxic cells.1 Progesterone has been observed to inhibit in vitro cytotoxic cell activity.3, 12 A balance between maternal cellular cytotoxicity and trophoblast progesterone production may exist at the maternal-fetal interface, thereby allowing for fetal survival. Immunoactivation of cytotoxic cells by IL-2 augments their ability to lyse trophoblast target cells.4,5

The mechanism of progesterone immunosuppression is unclear. Previous reports suggest that a classic progesterone receptor-mediated process may not be involved.13 We have demonstrated that progesterone's suppression of cytotoxicity is not due to target cell membrane stabilization. In our study the effector cells used were a heterogeneous population of mononuclear cells. Because cytotoxic cells may be driven by macrophage IL-1 and because progesterone in vitro suppresses monocyte IL-1 production,14,15 one could speculate that progesterone inhibits cytotoxicity indirectly by decreasing macrophage IL-1 production and subsequent activation of cytotoxic cells.

Evidence suggests that preeclampsia may be an immunoactivated state. Musci et al.6 demonstrated that mitogenic activity was significantly increased in prepartum, preeclamptic sera compared with controls. Elevated sera levels of IL-2 and interferon gamma were recently observed in patients with preeclampsia.17 Rodgers et al.8 noted that serum from women with preeclampsia is cytotoxic to endothelial cells in vitro, and both immunoglobulin G and immunoglobulin M antiendothelial cell antibodies have been reported in the sera of women with severe preeclampsia.9 With specific attention to cytotoxic immune mechanisms, Toder et al.10 demonstrated an increase in natural killer cell activity in women with preeclampsia, although contrary results have been reported.16 If the presumed lymphocyte-trophoblast immune balance at the maternal-fetal interface is to be maintained, then an increase in trophoblast production of progesterone would be expected in the face of maternal cytotoxic cell activation. Such a compensatory trophoblast response would be of evolutionary importance to ensure placentation in the presence of adverse host conditions. Preeclampsia is seemingly associated with maternal immune activation; therefore it is interesting to note coincidentally that preeclampsia placentas produce more progesterone in vitro than do normal placentas.11

In conclusion, we have demonstrated that progesterone inhibits cytotoxicity from both normal and IL-2-stimulated mononuclear cells. In the immunoactivated state significantly higher concentrations of progesterone are required to achieve suppression of cytotoxicity, to levels comparable to those of the normal, unstimulated state. Estrogens and progesterone can act synergistically when combined to suppress cytotoxicity, thereby requiring lower concentrations of each individual steroid. We speculate that the increased placental production of progesterone seen in preeclampsia may represent a trophoblast compensatory response to maternal immune activation.

Sister chromatid exchange frequency in directly prepared cytotrophoblasts: Demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes

Lee P. Shulman, MD, Sherman Elias, MD, Avirachan T. Tharapel, PhD, Lirong Li, PhD, Owen P. Phillips, MD, and Joe Leigh Simpson, MDa

Memphis, Tennessee

Assessing frequency of sister chromatid exchange is a sensitive method of monitoring exposure to clastogens, mutagens, and other substances that induce deoxyribonucleic acid damage. Aware that cigarette smcke is associated with increased sister chromatid exchange in many cell types, we sought to determine whether an in vivo effect of cigarette smoke could be demonstrated by study of sister chromatid exchange in chorionic villus cells. Directly prepared cytotrophoblasts and cultured mesenchymal core cells were analyzed. Mean sister chromatid exchange frequency in cytotrophoblasts from smoking subjects (8.87 sister chromatid exchanges per cell) was significantly greater than in nonsmoking subjects (5.81 sister chromatid exchanges per cell; p < 0.001); however, no significant difference in cultured mesenchymai core cells was found. Our results demonstrate that maternal exposure to cigarette smoke results in direct placental deoxyribonucleic damage, which in turn could explain deleterious effects of smoking on pregnancy. Increased sister chromatid exchange frequency was observed only in directly prepared cytotrophoblasts, showing the necessity of using this cell type to evaluate the effects of clastogens on placentas. (Am J OBSTET GYNECOL 1991;165:1877-80.)

Key words: Chorionic villi, cigarette smoke, sister chromatid exchange, prenatal diagnosis

Assessing frequency of sister chromatid exchange is a method of monitoring exposure to clastogens, mutagens, and other substances that induce deoxyribonucleic (DNA) damage.1,2 Although cigarette smoke has been associated with increased sister chromatid exchange frequency in many cell types,3,4 to our knowledge there have been no previous attempts to evaluate the in vivo effect of cigarette smoke on chorionic villi. We thus sought to compare sister chromatid exchange frequencies in directly prepared cytotrophoblasts and cultured mesenchymal core cells from chorionic villi obtained from both smoking and nonsmoking women to assess placental DNA damage resulting from cigarette smoke. We have previously shown that baseline sister chromatid exchange rates differ between directly prepared cytotrophoblasts and cultured mesenchymal core cells derived from the same villi5; accordingly, both cell types were investigated in our study.

Material and methods

Chorionic villi were obtained in the first trimester from women undergoing either chorionic villus sampling or pregnancy termination. A detailed cigarette smoking history was obtained before the procedure, and a peripheral blood sample (5 ml) was obtained for thiocyanate assay to verify smoking status.6 After aneuploid complements were excluded, all other chorionic villus specimens were coded so that laboratory personnel were unaware of medical or smoking history.

Both directly prepared cytotrophoblasts and cultured mesenchymal core cells were then analyzed as previously described.5 Briefly, villi were cleaned and incubated in complete medium (Alpha-minimal essential medium) supplemented with 15% Chang medium, 15% fetal bovine serum, 100 IU/ml penicillin, 100 μg/ml streptomycin, and 1% L-glutamine) at 37° C for 15 hours. Thereafter, intact chorionic villi were exposed to 5-bromo-2'-deoxyuridine for 72 hours at a final concentration of 30 µg/ml.

Relevant to this study is that in our cytogenetic method cytotrophoblasts and mesenchymal core cells are each are derived from the same villi rather than from different portions of a given specimen.7 To

achieve this, chorionic villi were first treated with trypsin—ethylenediaminetetraacetic acid to facilitate separating cytotrophoblasts from the mesenchymal core. Cytotrophoblasts were then detached by vigorously flushing villi in a Pasteur pipette. Remaining portions of villi represent the mesenchymal core, which were used to initiate long-term cultures. Cytotrophoblasts were then harvested and chromosome preparations were made after treatment with colcemid for 30 minutes.

Mesenchymal core cells derived from the same villi were allowed to remain in culture for approximately 12 days. These cells were then subcultured and 5 to 6 hours later exposed to 5-bromo-2'-deoxyuridine (final concentration 30 µg/ml) for 48 hours. Harvesting and chromosome preparations were performed in a manner similar to that used for cytotrophoblasts. Differential staining for sister chromatid exchange in cytotrophoblasts and mesenchymal core cells was according to the method of Perry and Wolff.⁸

Results

A total of 24 specimens were submitted for sister chromatid exchange analysis; 10 were obtained from patients undergoing chorionic villus sampling (10.8 to 12.7 weeks' gestation) and 14 from patients undergoing pregnancy termination (8.1 to 13.0 weeks' gestation). Three specimens, all obtained from patients undergoing pregnancy termination, were not analyzed because of their aneuploid chromosome complements. Mean sister chromatid exchange frequencies were ob-

tained from directly prepared cytotrophoblasts and cultured mesenchymal core cells for each of the 21 analyzed cases. Twenty cells were analyzed from each preparation.

Among the 21 cases analyzed, seven samples were obtained from smokers and 14 from nonsmokers. Each of the seven smoking women used at least 10 cigarettes daily; the 14 nonsmokers reported using no tobacco products (including smokeless products) for at least 6 months before chorionic villus sampling or pregnancy termination. All smokers had thiocyanate levels >55 mg/L (mean \pm SD 74 \pm 12.4 mg/L), whereas all nonsmokers had levels <30 mg/L (mean \pm SD 19.6 \pm 6.7 mg/L).

Mean sister chromatid exchange frequency for directly prepared cytotrophoblasts in smokers was 8.87 ± 1.05 (mean ± SD sister chromatid exchanges per cell), significantly greater than the frequency for directly prepared cytotrophoblasts obtained from nonsmokers $(5.81 \pm 0.89; p < 0.001, two-sample t test)$ (Table I). By contrast, sister chromatid exchange frequencies of cultured mesenchymal core cells in smokers and nonsmokers were not significantly different, 10.5 ± 0.38 and 10.18 \pm 0.45, respectively (p = 0.122; two-sample t test). In addition, sister chromatid exchange frequencies in cytotrophoblasts and mesenchymal core cells were significantly different, thus confirming results of our previous study.5 This difference was observed irrespective of whether chorionic villi were obtained from smokers (p < 0.01; two-sample t test) or nonsmokers (p < 0.001; two-sample t test).

Comment

Increased frequency of sister chromatid exchange has been shown to be a sensitive indicator of DNA damage in a variety of tissues, 9, 10 evaluating the clastogenic and mutagenic effects of drugs and environmental toxins.11 Increased frequency is also associated with certain chromosome breakage syndromes (e.g., Bloom syndrome, xeroderma pigmentosum).12,13 Sister chromatid exchange studies in humans have, in general, been limited to analysis of lymphocytes,4.9,10,14 although other tissues have been studied. 15, 16 Lukusa et al. 15 found no significant intraindividual or interindividual variability in sister chromatid exchange frequencies of human lymphocytes, whereas their similar analysis of human fibroblasts revealed significant interindividual variability. Thus analysis of fibroblasts probably should be avoided for comparisons of sister chromatid exchange frequences between individuals. Moreover, fibroblast analysis precludes in vivo assessment, for in vitro culturing is required in this tissue. For this reason, we investigated chorionic villi, a tissue amenable to direct and culture cytogenetic analyses. Our group⁵ first demonstrated that background frequencies differ between directly prepared cytotrophoblasts and cultured mesenchymal core cells. We were thus prepared to analyze frequency of both cell types after in vivo exposure to cigarette smoke.

Our current data demonstrate a significant increase in sister chromatid exchange frequency in directly prepared cytotrophoblasts obtained from women who smoke at least half of a pack of cigarettes per day. This is consistent with previous studies of the effect of smoking on frequency in maternal and fetal lymphocytes3,4; however, our results are indicative of direct placental DNA damage, which in turn could explain the deleterious effects of smoking on pregnancy, such as intrauterine growth retardation17 and late fetal and early neonatal death.18 That the increase in sister chromatid exchange frequency was found solely in cytotrophoblasts further verifies the in vivo effect on the placenta. This finding shows the desirability of using directly prepared cytotrophoblasts to evaluate the potentially deleterious effects of toxins on placentas.

Ability to analyze sister chromatid exchange frequencies in chorionic villus cells could prove useful for first-trimester prenatal diagnosis of chromosome breakage syndromes (e.g., Bloom syndrome, xeroderma pigmentosum), supplanting current techniques for prenatal diagnosis that require either amniocentesis or fetal blood sampling in the second or third trimester. 19, 20 Moreover, sister chromatid exchange analysis of placental tissue also could allow first-trimester evaluation of clastogens or mutagens that potentially affect fetal growth and development. Although our results indicate that sister chromatid exchange frequencies of cultured mesenchymal core cells do not reflect exposure to toxins such as cigarette smoke, further studies are needed to assess the applicability of both chorionic villus cell types for prenatal diagnosis of chromosome breakage syndromes and exposure to mutagens or clas-

We conclude that assessing sister chromatid exchange frequencies in directly prepared cytotrophoblasts is a sensitive indication of in vivo maternal-fetal exposure to cigarette smoke. Our findings further suggest that deleterious effects of smoking could be mediated by direct placental DNA damage.

Editors' note

The AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY introduces a new format for abstracts accompanying regular articles, society articles, and Current Investigation articles. Authors submitting these manuscripts to the JOURNAL should provide an abstract of no more than 150 words structured according to the following headings: Objective(s), Study Design, Results, and Conclusion(s). Exceptions to this requirement include Clinical Opinion, Current Development, case report, and brief communication articles. Abstracts for these articles will continue to follow the standard abstract format. Please consult the Information for Authors for details.

Cellular localization of müllerian inhibiting substance messenger ribonucleic acid during human ovarian follicular development

Gail F. Whitman, MD,* and Cooley G. Pantazis, MDb

Augusta, Georgia

Müllerian inhibiting substance is expressed in the human reproductive system and has been associated with oocyte meiotic arrest. In situ hybridization was used to selectively localize ovarian cells containing high levels of müllerian inhibiting substance messenger ribonucleic acid, a müllerian inhibiting substance precursor, during different stages of human follicular development. Müllerian inhibiting substance transcript was noted in the granulosa cells of primordial, primary, and antral follicles. Surprisingly, transcript was also identified within the cytoplasm of oocytes and throughout the ovarian stroma. Controls included sense oligoprobe, positive and negative tissue controls, and treatments minus the detection antibody. Localization of transcript within the cytoplasm demonstrates that active transcription of müllerian inhibiting substance messenger ribonucleic acid occurs within both fetal and adult human female gonads. The presence of müllerian inhibiting substance messenger ribonucleic acid within oocyte cytoplasm could implicate an autocrine role for müllerian inhibiting substance-derived peptides in the establishment of oocyte competence. (AM J OBSTET GYNECOL 1991;165:1881-6.)

Key words: Müllerian inhibiting substance (MIS), oocyte competence, in situ hybridization, messenger ribonucleic acid (mRNA), digoxigenin

Müllerian inhibiting substance is a glycoprotein associated with the regression of müllerian primordia in male embryos1 and with the sex reversal of freemartin gonads.24 Although this protein was initially thought to be expressed only in male fetuses, abundant evidence now exists suggesting that müllerian inhibiting substance plays some role in normal ovarian physiologic composition.5,6 The bioactive protein7 and messenger ribonucleic acid (mRNA) transcript8 for müllerian inhibiting substance have been identified in adult mammalian ovaries. Moreover, a sensitive radioimmunoassay has detected low levels of müllerian inhibiting substance in the cord blood of human female newborns with higher amounts detected in the sera of girls in later childhood, adolescence, and adulthood.9 The gene coding for müllerian inhibiting substance has been cloned, 10-12 sequenced, 10-12 and mapped to an autosome, chromosome 19 subband p13.2-p13.3.13

Takahashi et al.14 postulated that müllerian inhibiting

substance may serve as a meiotic inhibitor after demonstrating the absence of meiosis reactivation in mature rat oocytes exposed to the natural bovine hormone. Subsequently, others showed that human recombinant müllerian inhibiting substance can also inhibit meiosis in rat oocytes in vitro and that the addition of epidermal growth factor, an apparent müllerian inhibiting substance antagonist,15,16 can reverse this inhibition.17 Although the mechanism of this inhibition remains open to speculation, it is clear that further studies designed to uncover the full nature of müllerian inhibiting substance gene expression in the ovary are necessary. We recently elected to use in situ hybridization to selectively localize human ovarian cells containing high levels of müllerian inhibiting substance mRNA, a müllerian inhibiting substance precursor. This technology allows for the detection of small quantities of specific ribonucleic acid transcript within the cell of origin while maintaining histologic integrity of the tissues. 18 Because folliculogenesis is initiated during fetal life in the human,19 we studied ovaries at different stages of fetal and postnatal development.

Material and methods

Specimens. Formalin-fixed, paraffin-embedded archival ovaries from a 21-week fetus, a 40-week fetus, a 5-month-old infant, and a 26-year-old woman were provided by the Pathology Department at the Medical College of Georgia after clearance by the institutional

Human Assurance Committee. All tissue blocks evaluated appeared morphologically normal, had no evidence of autolysis, and exhibited little or no fixation artifact on initial histologic screening. All tissue blocks were taken from autopsies done after Jan. 1, 1989. By departmental protocol all specimens were fixed in formalin within 6 hours of receipt. Additionally, a fresh ovarian specimen was obtained, formalin fixed, paraffin embedded, and included in our observations. This specimen was obtained from a 5-month-old baby who died of secondary complications of bronchopulmonary dysplasia.

Briefly, 5 μ m tissue sections were mounted on slides pretreated with a 2% solution of 3-aminopropyltriethoxysilane (silane) in acetone (Sigma, St. Louis). The sections were then deparaffinized in xylene and exposed to absolute alcohol for 3 minutes, then 95% alcohol for 3 minutes.

Positive and negative tissue controls were generated from a first-trimester 6 cm crown-rump length bovine fetal testis²¹ and adult rat hearts, respectively. These tissues were dispersed with a 25 mg/100 ml collagenase mixture (Cooper Biomedical, Malvern, Pa.) for 20 minutes at room temperature. After digestion the cells were washed twice with phosphate-buffered saline solution and 5 mmol/L magnesium chloride (Gibco-BRL, Gaithersberg, Md.). Dispersed cells were spun into monolayers and affixed to silane-treated slides with the Cytospin 2 apparatus (Shandon, Pittsburgh). They were then fixed in 4% paraformaldehyde (Sigma) for 10 minutes at room temperature. This was followed by two 15-minute washes in phosphate-buffered saline solution.

To destroy endogenous alkaline phosphatase activity and make the mRNA accessible, affixed tissue sections and control cell monolayers were exposed to 1 µg/ml proteinase K (Boehringer Mannheim Biochemicals, In-

dianapolis) in phosphate-buffered saline solution for 5 minutes at room temperature, washed with 0.2% glycine (Biorad, Richmond, Calif.) in phosphate-buffered saline solution for 10 minutes, and dried completely on a slide warmer at 37° C.

Experimental runs included controls with positive and negative tissue controls, sense oligoprobe, and treatments minus the detection antibody.

Probes. Sense and antisense oligoprobes complementary and unique to the first 27 bases of exon 5 of the human müllerian inhibiting substance gene^{8, 10, 11} were synthesized on an Applied Biosystems, Inc. (Foster City, Calif.) model 380B DNA synthesizer in the laboratory of Terrance Stoming, PhD. These sequences were chosen because they contain an abundance of guanine and cytosine residues,10,11 they have been used successfully for Northern blot analysis by other investigators,8 and are unique to the published human müllerian inhibiting substance gene sequence10,11 according to the Genebank and EMBL databases. A nonradiolabeled detection system was used. With this system a standard reaction with 1 µg of deoxyribonucleic acid (DNA) as template will generate a minimum of 260 ng of labeled probe (Boehringer Mannheim). For this series of experiments end labeling with digoxigenin-11-2'-deoxyuridine 5'-triphosphate (Boehringer Mannheim) was accomplished via terminal transferase (Boehringer Mannheim) at 37° C for 11/2 hours.22 Probes obtained with this procedure can be used to detect about 10 pg of DNA in a dot blot.

Hybridization. Ten microliters of hybridization mixture was added to each slide. The hybridization mixture consisted of 50 µl of deionized formamide, pH 6.8 (Biorad), 20 µl of 50% dextran sulfate (Pharmacia LKB Biotechnology, Piscataway, N.J.), and 10 μl of 20× sodium chloride citrate (SCC) (Sigma), plus 20 mm³ of probe carrier mix. The probe carrier mix consisted of 4 μl of desired probe (500 ng in 20 μl), 8 μl of 0.5 mg/ml salmon sperm DNA (Boehringer Mannheim), and 8 µl of 0.25 mg/ml yeast transfer RNA (Boehringer Mannheim). Silicon-treated coverslips (Sigma) were applied to the specimens, which were placed into hybridization bags (Bethesda Research Laboratory, Bethesda, Md.) and heat sealed. The tissue with added probe was heated for 10 minutes in an 85° C water bath, then allowed to hybridize in a humidified 40° C oven for 18 hours.28 Coverslips were removed by soaking the specimen in $2 \times SCC$ ($1 \times SCC = 0.15 \text{ mol/L}$ sodium chloride and 0.015 mol/L sodium citrate). Unhybridized probe was removed by a series of graded salt washes at room temperature: twice with 2× SCC/Brij for 3 minutes, twice with 0.2× SCC/Brij for 3 minutes, twice with 0.16× SCC/Brij for 3 minutes, and with a final wash of 2 × SCC for 1 minute. Brij (Calbiochem, La Jolla, Calif.) is 2.5 ml/L of 30% Brij 35).23 Constant conditions were maintained throughout all experi-

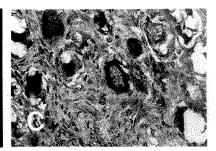

Fig. 2. Same section as in Fig. 1 at higher magnification. Highest staining intensity was noted in primordial oocytes. A, Müllerian inhibiting substance antisense probe. (Original magnification ×10.) mental runs except for changes in probe concentration. Probe concentration was manipulated from 10 to 50 ng/μl in an effort to improve signal detection.

Detection. Alkaline phosphatase-conjugated Fab fragments from digoxigenin-induced immunoglobulin in sheep were used to detect hybridized fragments labeled with digoxigenin. In the presence of nitro blue tetrazolium chloride (Sigma) and 5-bromo-4-chloro-3indolyl phosphate (Sigma) a blue-purple reaction product is generated. The specimens were blocked with 3% bovine serum albumin in Trizma-saline buffer (Sigma), washed for five minutes in Trizma-saline buffer, air dried, and exposed to either a 1:500 dilution of antidigoxigenin antibody (Boehringer Mannheim) or control normal sheep serum (Cambridge Research Laboratories, Cambridge, Mass.). Antibody dilutions were carried out for 2 hours at room temperature in humidity chambers. One microliter of antibody was added to a mixture of 20 mg bovine serum albumin, 500 µl Trizma-saline (pH 7.5), and Tween 20 (Sigma), total volume 1.25%.23 The specimens were then washed three times for 3 minutes each in Trizma-saline, pH 7.5, containing 0.1% Triton X-100 (Sigma). These washes were followed by two 5-minute washes in Trizma-saline, pH 9.5 (50 mmol/L magnesium chloride).

Color development was completed under dark conditions by exposure to McGadey's reagent mixture for 2 hours. This mixture consisted of 0.2 ml (50 mg nitro blue tetrazolium chloride per milliliter 50% deionized formamide), 0.1 ml (50 mg 5-bromo-4-chloro-3-indolyl phosphate per milliliter 50% deionized formamide), and 30 ml Trizma-saline, pH 9.5. The sections were then counterstained with nuclear fast red, dehydrated, and mounted with Cytoseal 60 (Stephens Scientific, Denville, N.J.).

Results

Unexpectedly, the most intense signal generated in the ovary was noted within the nuclei of several resting

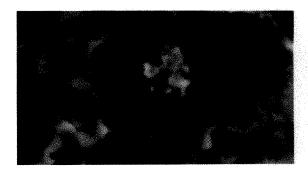

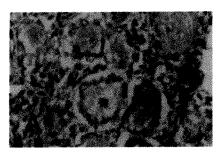

Fig. 3. Different section from same ovary showing two adjacent primordial follicles exposed to müllerian inhibiting substance antisense probe. Pregranulosa cells appear red with staining. Follicle on right demonstrates selective staining confined to cytoplasm. Adjacent follicle demonstrates both nuclear and cytoplasmic staining. (Nuclear fast red. Original magnification ×400.)

primordial oocytes (Figs. 1 through 3). Positive staining was also noted within the cytoplasm of oocytes exposed to the antisense probe. The highest level of cytoplasmic staining was seen in oocytes from primordial follicles. Oocytes within antral follicles from the same tissue sections appeared to have a much lower level of reaction product (Figs. 1 through 4). Semiquantitation for comparison was not attempted, however, because of the small number of antral follicles in the specimen studied.

A lower level of staining was detected within granulosa cells and the ovarian stroma (Figs. 1 through 4). All ovarian cells had some detectable reaction product except for endothelial cells lining blood vessels. This reaction product did not appear to be artifact because matched sense probe sections were negative. An identical staining pattern was demonstrated with the fresh ovarian specimen. The antisense probe stained the bovine fetal testis-positive tissue control more intensely than any of the ovarian sections (Fig. 5). No staining was noted in the adult rat heart-negative tissue control (not shown). As expected, none of the tissue sections or tissue controls stained positively with the sense probe or with the absence of detection antibody.

Comment

Utilizing Northern blot analysis, Voutilainen and Miller⁸ detected small, unchanging amounts of human müllerian inhibiting substance mRNA in the extracted RNA from ovaries of 14- to 21.5-week human fetuses. They⁸ further demonstrated that cells from follicular aspirates obtained during oocyte retrieval for in vitro fertilization transcribe müllerian inhibiting substance mRNA in a hormonally responsive fashion. Our work confirms the fact that a small amount of müllerian inhibiting substance transcript is generated by cells in the female gonad throughout human life. It appears, however, that several ovarian cell types participate in this transcription.

One site of localization was the granulosa cells. This was not unexpected because several investigators^{7, 24, 25} have demonstrated immunoreactive müllerian inhibiting substance protein in the granulosa cells of growing follicles. However, müllerian inhibiting substance transcript also was detected in oocytes and ovarian stromal cells. It is doubtful that this localization is the result of nonspecific binding because the appropriate hybridization signals were generated in control tissues and

short oligoprobes specific to the published sequence were used to reduce hybridization to undesired transcripts sharing close sequence homology to müllerian inhibiting substance mRNA.²⁶ Because of institutional restrictions on human fetal research, we used archival tissue. Special care was used to select tissue blocks that were well preserved. Although it is possible that ribonuclease digestion occurred before tissue preservation, the use of short oligoprobes to detect transcript makes it possible to identify specific messages in spite of less than ideal conditions.²⁶ We have avoided attempts to quantify the amount of transcript detected because of possible variations in tissue handling and nucleic acid retention in archival specimens.

Both granulosa and ovarian stromal cells share embryologic origins from mesonephric-derived rete cells destined to participate in ovarian steroidogenic function.²⁷ Granulosa cells demonstrate müllerian inhibiting substance gene expression subject to cell-specific regulation with the production of müllerian inhibiting substance protein.⁷ ⁸ Oocytes, on the other hand, are descendants of primitive germ cells and serve a totally different function.²⁸ These cells must establish genetic

variation, generate many of the substances necessary for oocyte fertilization, and store materials for future support and regulation of the preimplantation conceptus.28 Active müllerian inhibiting substance transcription within the oocyte suggests some physiologic role. Whether this role involves autocrine regulation of oocyte competence is speculative. If müllerian inhibiting substance protein is involved in the maintenance of meiotic arrest as proposed by Takahashi et al,14 one might expect to detect the most significant levels of ovarian müllerian inhibiting substance protein production during the time when most oocytes are present in the dictyotene stage. This would be during the latter part of human fetal development. 19, 28 To date immunoreactive müllerian inhibiting substance protein has not been detected in any mammalian oocytes. This could be due to the fact that the amounts of translated protein may be too small to detect with generated müllerian inhibiting substance antibodies or to epitope differences between the fetal and adult product. However, it is quite possible that oocyte müllerian inhibiting substance transcript is not translated until after fertilization events take place. The oocytes of many species have been shown to store deadenylated RNA for subsequent use after fertilization.29

It is interesting that müllerian inhibiting substance belongs to the transforming growth factor-\beta family of proteins, 10, 30 which includes the Vg1 gene product, an oocyte protein associated with mesoderm induction during early Xenopus development.30 Could it be that oocyte müllerian inhibiting substance transcript, like several other transforming growth factor-\beta family members, plays some role in the diversification of cell fate during embryonic cleavage? Further investigations are currently under way to elucidate this most interesting possibility.

The presence of the testicular determining sequence, SRY, in 46,XY females with gonadal dysgenesis (Swyer syndrome)

M. Ali Behzadian, PhD, a, b, c Sandra P.T. Tho, MD, a, c and Paul G. McDonough, MDa, c Augusta, Georgia

Subjects with 46,XY gonadal dysgenesis (Swyer syndrome) have a distinctive phenotype. They are normal or tall in stature, lack somatic anomalies, and possess bilateral rudimentary gonads. Critical Yp deletions have been described in some cases, but in the majority no defects at the molecular level have been reported. To verify the presence or absence of SRY, the putative testicular-determining factor gene, specific primers were designed to amplify the conserved region of the SRY gene. Deoxyribonucleic acid from control males (n=10) and sex-reversed females with the Swyer syndrome phenotype (n=5) generated the anticipated 310 bp band. This Y-specific band was absent in the deoxyribonucleic acid from control females (n=9). To search for possible point mutations, the amplified products of all study subjects and one control male were sequenced in both orientations. The base pair sequences were all identical and similar to the previously published report. (AM J OBSTET GYNECOL 1991;165:1887-90.)

Key words: Testicular determining factor, sex-reversed females, pure gonadal dysgenesis, Swyer syndrome

In man, differentiation of the testis from the embryonic biopotential gonad (genital ridge) is primarily initiated by the expression of a Y-associated gene(s) called the testicular-determining factor.1-7 This putative factor probably activates a succession of autosomal genes that switch the inherently female pattern of development to that of the male, beginning with testis formation followed by production of müllerian-inhibiting factor and testosterone. The assignment of testicular-determining factor to the Y-chromosome short arm has been possible by studying sex-reversed individuals—XY females with Yp deletions and XX males with Y/X translocation chromosomes. 1. 3-6 By deletion analysis of an XX male carrying the distal part of the Y short arm and a female with a Y-autosomal translocation missing the same region, Page et al.4 isolated a 140 kb fragment of the Y chromosome that encodes a "zinc finger" protein. The gene, designated ZFY, which is highly conserved among mammals, became the prime candidate for testicular-determining factor. Later, however, three XX males and one XX intersex individual were discovered who are missing ZFY and instead carry a fragment of Y deoxyribonucleic acid (DNA) distal to the ZFY locus.⁶ A 35 kb segment was cloned from the region that seemed to contain the essential element(s) required to initiate male sex determination. In this 35 kb region, so far only one gene, designated SRY, has been located. This gene is Y specific, highly conserved among mammals, and transcribed only in testis.7 The predicted amino acid sequence of SRY shares homology with DNA-binding domains of transcription factors such as chromatin-associated, nonhistone proteins HMG 1 and HMG 2. Gubbay et al.8 cloned the SRY-related gene Sry from the mouse Y chromosome and showed that it is exclusively expressed in the mouse embryonic gonad. Most recently a 14 kb mouse Y-chromosomal DNA that carries the Sry gene region was introduced into mouse embryos to obtain transgenic animals that could express and vertically transmit the integrated Sry gene. Three of 11 XX transgenic animals showed sex-reversed phenotypes, which argues that the 14 kb fragment includes the essential information required for male sex determination in the mouse. However, when a 25 kb human Y-DNA fragment including the SRY gene was introduced, the transgenic animals showed no sex reversal.9

Although *Sry* seems to fulfill the criteria for the testisdetermining gene, further analysis of the human SRY gene and studies of phenotype-genotype correlations in subjects with abnormal sex differentiation will help to better clarify the mechanism of action of regulatory and structural genes involved in sex differentiation. In this regard testing the integrity of the SRY gene in 46,XY females is of considerable interest. In this study the DNA of a group of 46,XY females, carefully selected for the Swyer syndrome phenotype and devoid of all somatic anomalies, was analyzed for the presence of SRY and its integrity. Such sex-reversed females

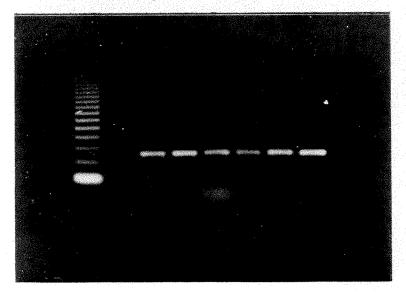

Fig. 1. Polymerase chain reaction amplification of SRY sequence from five patients with Swyer syndrome as compared with normal male (M) and female (F) samples. The 310 bp polymerase chain reaction products are stained with ethidium bromide in 1.2% agarose gel. Band is absent in control female sample. SRY primers 5'-GTGTGAAACGGGAGAAAA CAGTAAA-3' and 5'-ATCTGCGGGAAGCAAACTG-3' were synthesized with a Pharmacia-LKB Gene Assembler Plus (Piscataway, N.J.). Reaction was carried out for 30 cycles at annealing temperature of 55° C, and 8% of end products were used for electrophoresis.

could have simple mutations in the SRY gene; alternatively, they could have mutations that block gene actions further upstream or downstream in the cascade responsible for male differentiation.

Material and methods

Patients. Written informed consent was obtained from each patient participating in the study, as approved by the Human Assurance Committee at the Medical College of Georgia. The 46,XY sex-reversed females (n = 5) selected for this study were all sporadic cases, devoid of somatic, cardiac, or renal anomalies, and ranged in adult height frrom 167 to 190 cm (mean 173.8 cm). Serum gonadotropin levels were markedly elevated in all five subjects. Peripheral blood karyotyping with 50 cells counted revealed a uniform 46,XY karyotype with a structurally normal Y chromosome on G, Q, and C banding. Bilateral rudimentary streak gonads were present at laparotomy in all cases, except for three where they were unilaterally replaced by tumor.

DNA analysis by polymerase chain reaction amplification. The DNA of the study subjects was analyzed by the polymerase chain reaction for the presence or absence of SRY. Nucleotide positions of primers relative to the sequence published by Sinclair et al.7 were 543 to 569 for 5', and 833 to 854 for 3', flanking a 312 bp segment, including the coding domain of the SRY gene. DNA samples from various sources such as blood lymphocytes, skin fibroblasts, or Epstein-Barr virustransfected lymphoblastoid cells were examined from each individual, depending on availability. The polymerase chain reaction was carried out in a total volume of 100 µl with 1 µg of DNA in 10 mmol/L Tris, pH 8.3, 1.2 mmol/L magnesium chloride, 50 mmol/L potassium chloride, 0.01% gelatin, 250 µmol/L each dNTP, and 3.3 units of Taq polymerase (Thermus aquaticus; Perkin Elmer/Cetus, Norwalk, Conn.) in the presence of 0.5 µmol/L primers. In the initial cycle denaturation was at 96° C, annealing at 55° C, and extension at 72° C, each for 5 minutes. This was followed by 30 cycles of 3, 2, and 5 minutes for each denaturation, annealing, and extension step, respectively, with a final extension step of 10 minutes in the last cycle.

Asymmetric polymerase chain reaction and DNA sequencing. For sequencing, the SRY fragment was amplified from each DNA sample as above. One microliter of each of the end products was transferred to a freshly prepared polymerase chain reaction containing only one of the primers, and the amplification reaction was 5'-gtgtgaarc ggagaarca gtaaaggca cgtccagat agagtgaagc gacccatgaa CGCATTCATC GTGTGGTCTC GCGATCAGAG GCGCAAGATG GCTCTAGAGA ATCCCAGAAT GCGAAACTCA GAGATCAGCA AGCAGCTGGG ATACCAGTGG ARAATGCTTA CTGAAGCCGA AAAATGGCCA TTCTTCCAGG AGGCACAGAA ATTACAGGCC ATGCACAGAG AGAAATACCC GAATTATAAG TATCGACCTC GTCGGAAGGC GAAGATGCTG CCGAAGAATT GCAGTTTGCT TCCCGCAGat-3'

Fig. 2. Nucleotide sequence of 310 SRY coding domain amplified from five sex-reversed females and one normal male. Asymmetric polymerase chain reaction was performed for 50 cycles with 1 mm³ of polymerization products described in Fig. 1 as template, with the addition of only either forward or reverse primers. Purified asymmetric polymerase chain reaction products were then used for sequencing by standard dideoxy termination method of Sanger with the Sequenase II kit. *Arrows* show primers and direction of amplification. *Bold uppercase letters* show sequenced nucleotides, whereas *lowercase letters* indicate nucleotides that were present in primers but were not sequenced.

carried out for 50 cycles to generate single-stranded DNA of both orientations. DNA sequencing was performed with the Sequenase kit (USB Co., Cleveland).

Results

All of the subjects and 10 male control DNA samples were positive whereas nine female control samples were negative for the 312 bp band that represents the coding sequence of SRY (Fig. 1). Samples from normal females occasionally formed a very weak band of lower molecular weight, but none of them revealed the specific band found in males and in the 46,XY sex-reversed females studied. Since SRY codes for a conserved 80 amino acid motif with great homology with a family of transcription factors encoded by autosomes, we sequenced the amplified fragments from all patients and one normal male to confirm that the amplified regions actually represent the Y-chromosome sequence. The results precisely matched the sequence published by Sinclair et al.7 (Fig. 2). These data also rule out the presence of a point mutation in the coding domain of the SRY gene as a possible cause of sex reversal in these XY females.

Comment

Although SRY appears to fulfill the criteria for the testis-determining gene, it has not been excluded that some other gene may exist in the 35 kb Y fragment found in the XX males studied by Sinclair et al. and Berta et al. Furthermore, although testes developed in these ZFY-negative XX males, male genitalia were not fully developed. In the mouse the sex-determining region of the Y is now clearly defined within a 14 kb fragment capable of rendering the XX transgenic animals male; however, it is not clear why only three of 11 transgenic animals showed sex-reversed phenotypes. Furthermore, none of the transgenic animals carrying the 25 kb fragment, including the human SRY, showed sex reversal.

If SRY is testicular-determining factor, 46-XY sexreversed females with intact Y chromosomes may have missing or mutated SRY sequences. Berta et al.10 examined the SRY DNA sequence in 11 sex-reversed females and found only single-base substitutions in two of them $(G \rightarrow A \text{ in one and } G \rightarrow C \text{ in the other})$. These base substitutions, however, are known to cause conservative amino acid changes. Notably, the normal father of one of these subjects was carrying the same single base substitution in his SRY.10 Jager et al.11 analyzed 12 sex-reversed females and found a frameshift mutation in one of them. This individual is tall in stature and has a 46,XY karotype and no evidence of mosaicism. To our knowledge, this is the only case reported with detailed ascertainment of pure gonadal dysgenesis in an individual with a defined mutation in SRY. Subjects with pure 46,XY gonadal dysgenesis (Swyer syndrome), if appropriately selected, should have a solitary anomaly, the failure of gonadal development. The gonads in patients with Swyer syndrome are undifferentiated streaks composed of fibrous tissue and devoid of germ cells. Because of the lack of gonadal steroids that allow delayed epiphyseal closure, the height of Swyer syndrome subjects is normal or increased, as compared with their 46,XX siblings, which distinguishes this syndrome from other forms of gonadal dysgenesis with the somatic signs of Turner syndrome associated with X monosomy or 45,X/46,XY mosaicism. Deletions of Yp have been described in some nonmosaic, 46,XY sex-reversed females. However, the presence of short stature and somatic anomalies in most of these reported cases suggests mosaic 45,X/46,XY gonadal dysgenesis rather than Swyer syndrome.1.3,12,13 According to the X,Y interchange model, the XY females should lack some terminal portion of Yp. Previously we have reported the presence of ZFY in these subjects,14 and the integrity of the new candidate sex-determining locus, SRY, is demonstrated here. Whether the SRY gene in these pure 46,XY subjects is inactive or they have other unidentified deletions remains to be seen. The presence of families in which Swyer syndrome appears to show X-linked inheritance¹⁸ also raises the question as to whether an X-linked gene that functions downstream from SRY is involved in creating the Swyer syndrome phenotype. These subjects, when carefully selected for their distinctive phenotype, provide the best opportunity to study the aberrations of gonadal development in man.

Evidence for a partial deletion in the androgen receptor gene in a phenotypic male with azoospermia

James W. Akin, MD, Ali Behzadian, PhD, Sandra P.T. Tho, MD, and Paul G. McDonough, MD

Augusta, Georgia

Androgen resistance is thought to vary phenotypically from a normal female to an infertile male. Previous evaluation of infertile males has been limited to androgen receptor—binding affinity. The androgen receptor gene has been isolated, cloned, and studied extensively in patients with complete androgen insensitivity syndrome, but no comparative data are available on infertile males. To address this matter, the androgen receptor gene was studied in seven azoospermic males by use of the polymerase chain reaction and Southern blot hybridization. A partial gene deletion was found in one patient. This study provides the first molecular evidence of an abnormality in the androgen receptor gene in a phenotypic male with azoospermia. (AM J OBSTET GYNECOL 1991;165:1891-4.)

Key words: Male infertility, azoospermia, androgen receptor, androgen insensitivity syndrome

The range of phenotypes in subjects with androgen resistance may vary from 46,XY sex-reversed females to undermasculinized normal males. Aiman et al.1 published a report in 1979 suggesting that phenotypically normal, infertile males also may be included in the spectrum of androgen insensitivity. They described 3 phenotypically normal men with semen abnormalities (2 azoospermic and 1 oligospermic) as having abnormal androgen receptor-binding affinity. A follow-up study by the same group2 reported on 22 phenotypically normal men with either idiopathic azoospermia or severe oligospermia. Abnormal androgen receptor-binding affinity was seen in 9 of 22 patients (8 azoospermic and 1 oligospermic). In 3 of the 9 patients with low androgen receptor activity the serum testosterone levels were elevated above normal. Their conclusions suggested that ≥40% of men with male infertility that is a secondary effect of azoospermia or severe oligospermia may have some degree of androgen resistance.

Bouchard et al.³ questioned this high prevalence of androgen resistance as a cause of infertility in males with normal phenotypes. Their study included 24 men with severe oligospermia. The testosterone values were all within the normal range. Fibroblasts were cultured and androgen receptor—binding affinities were normal in all patients. However, no patients with azoospermia were included in their report.

Presented at the Thirty-eighth Annual Meeting of the Society for Gynecologic Investigation, San Antonio, Texas, March 20-23, 1991. Reprint requests: Paul G. McDonough, MD, Department of Obstetrics and Gynecology, Medical College of Georgia, Augusta, GA 30912. 6/6/32385

Recent studies of androgen insensitivity syndrome have focused at the molecular level and limited the study population to subjects with complete androgen resistance. In 1988, Lubahn et al.4 reported the isolation and cloning of the gene for the androgen receptor. Shortly thereafter, the same group and others described the use of radiolabeled probes on Southern blots prepared by restriction endonuclease digestion of genomic deoxyribonucleic acid (DNA) to detect partial androgen receptor gene deletions in individuals with complete androgen insensitivity syndrome.5,6 This was followed by publication of the entire sequence of the eight exons present in the androgen receptor gene along with their intron-exon borders. Subsequent nucleotide sequencing of the androgen receptor gene in one patient with complete androgen insensitivity syndrome revealed a single point mutation.7 At least one additional article also describes the presence of a point mutation in a patient with complete androgen insensitivity syndrome.8 These studies have served to increase our understanding of the etiology of complete androgen insensitivity syndrome.

No comparative data at the molecular level are available on phenotypically normal males who might have infertility as a secondary effect of some degree of androgen resistance. The purpose of this study was to search for molecular evidence that might support this hypothesis.

Material and methods

Approval was given by the Human Assurance Committee at the Medical College of Georgia, and informed written consent was obtained from patients (n = 7) and controls (n = 1) to participate in the study. Peripheral

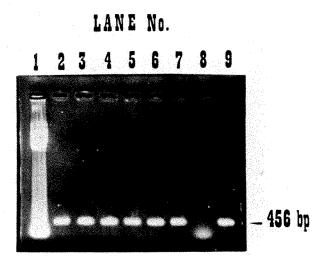

Fig. 1. Polymerase chain amplification of exon 4 of androgen receptor gene in azoospermic males. *Lane 1*, DNA ladder (multiples of 123 bp); *lane 2*, control male; *lanes 3 to 9*, azoospermic patients. *Lane 8* demonstrates absent band corresponding to exon 4.

blood was obtained by venipuncture, and DNA extraction was accomplished by standard techniques. Each patient had presented with infertility as a result of azoospermia. Clinical evaluation included a normal male phenotype, a 46,XY karyotype, including a morphologically normal Y, a normal serum testosterone level (300 to 800 ng/dl), a normal serum luteinizing hormone level (5 to 20 mIU/ml), a vasogram showing patency, and a testicular biopsy specimen revealing either germ cell aplasia or maturation arrest.

Polymerase chain reaction. According to the published sequence for the exons and immediately flanking introns of the androgen receptor gene, corresponding oligonucleotide primers identical to those used by Lubahn et al.⁷ were synthesized for each of the exons on the Gene Assembler Plus (Pharmacia). The primers ranged in size from 20 to 30 nucleotides. Purification of the primers was achieved by filtration through a Sephadex G-25 (Pharmacia) column.

The polymerase chain reaction was performed on each patient and control. Genomic DNA (1 µg) was added to a solution of reaction buffer consisting of 50 mmol/L potassium chloride, 10 mmol/L Tris hydrochloride (pH 8.3), 1.5 mmol/L magnesium hydrochloride, and 0.01% gelatin. Oligonucleotide primers (20 mmol/L), deoxyribonucleoside triphosphates (200 µmol/L each), and *Thermus aquaticus* DNA polymerase (1.5 units) were then added. Amplification was carried out on a DNA thermal cycler with initial denaturation at 95° C for 5 minutes, annealing at 55° C for 5 minutes, and polymerization at 72° C for 5 minutes. Next, 30 cycles of 1 minute at 95° C, 1 minute at 55°

C, and 1 minute at 72° C were performed followed by a final 5 minutes at 72° C. After amplification, the products were evaluated by size by means of gel electrophoresis.

Southern analysis. The probe hAR1, which is specific for the androgen receptor gene, was used for Southern analysis. It is a 718 bp EcoRI/HindIII complementary DNA (cDNA) fragment that contains a portion of the DNA binding domain at its 5'-terminus and extends into the 3'-steroid-binding domain (for map see reference 5). Genomic DNA digestion in normal patients yields two EcoRI fragments of 9.4 and 2.4 kb on Southern blots. The 9.4 kb fragment is thought to contain the information for exon 4.5 The probe was originally derived from clone ARHFLIH-X obtained from a human foreskin fibroblast cDNA library and inserted into a Bluescript SK+ vector.4 The plasmid was amplified in Escherichia coli and purified by cesium chloride gradient. The corresponding insert was released from the vector and labeled by oligonucleotide random priming to a high specific activity of 1×10^8 counts/min/ μ g DNA with the procedure recommended by the supplier (Amersham).

Genomic DNA from both the patients and the control was digested with EcoRI restriction endonuclease and samples of 10 µg each were electrophoresed in a 0.8% agarose gel. DNA was then transferred to Gene Screen Plus (New England Nuclear Research Products, Boston) by the Southern method¹⁰ and baked in a vacuum oven for 2 hours at 80° C. The blot was then hybridized for 48 hours at 65° C with a phosphorus 32–labeled probe and washed in high-stringency conditions at 65° C in 0.1 × sodium chloride—sodium citrate and 1% sodium dodecyl sulfate. Autoradiographs were exposed with intensifying screens at -80° C for 3 days on Kodak XAR-5 film (Eastman Kodak Company, Rochester, N.Y.).

Results

Evaluation of polymerase chain reaction—amplified exons, through the use of gel electrophoresis to determine product size, revealed no gross abnormalities in each of the 7 patients for exons 2 through 8 with only one exception. The product corresponding to exon 4 was absent in 1 patient (Fig. 1).

Southern analysis confirmed an abnormality in this same region of the androgen receptor gene as evidenced by an absent 9.4 kb band in the affected patient as compared with a control male (Fig. 2).

Comment

Aiman et al. first presented their theory of androgen resistance as a cause of male infertility in patients with normal phenotypes in 1979 and later studies have sup-

ported their hypothesis. Smallridge et al.¹¹ described oligospermic monozygotic twin brothers with normal male phenotypes who had decreased androgen receptor activity. This observation would imply a genetic basis for the oligospermia.

These reports suggest that androgen resistance is a cause for infertility; however, our study is the first to provide direct evidence for this hypothesis at the molecular level. Through the use of the polymerase chain reaction, an absent band corresponding to exon 4 of the androgen receptor gene in one azoospermic male was detected. The presence of this deletion is confirmed by the absence of the 9.4 kb band on the Southern analysis.

Exon 4 is thought to encode for the part of the androgen receptor protein that facilitates its movement into the nucleus of the target cell after binding to the steroid hormone. This hypothesis is based on in vitro studies in which induced mutations within exon 4 have been shown to interfere with cytoplasmic-to-nuclear migration of the androgen receptor-steroid complex but not the actual binding of the steroid hormone to the receptor. It is conceivable that the nuclear transfer of steroid-receptor complex in our affected subject is less efficient, resulting in lower androgen-dependent transcriptional activity of some target genes. This activity may be adequate for the male phenotypic expression but inadequate for proper germ cell function resulting in azoospermia.

We are aware of only two studies of complete androgen insensitivity syndrome where mutations involving exon 4 have been reported. The first describes a point mutation in the intron between exons 4 and 5 involving the splice donor site of intron 4. This abnormality is thought to result in a truncated messenger ribonucleic acid at the splice site and does not allow translation of exons 5 to 8. The second article describes three complete androgen insensitivity syndrome siblings, each carrying the same single point mutation within exon 4. This latter point mutation changes a tryptophan to a translation stop codon, again creating a truncated androgen receptor lacking most of its steroid-binding domain.

Complete exon deletions may result in frameshift errors that interfere with the translation of downstream exons, resulting in nonfunctional proteins. The dystrophin gene in most patients with Duchenne muscular dystrophy contains such a deletion. A resultant truncated protein is responsible for the severity of this disease. Conversely, patients with Becker muscular dystrophy frequently have a dystrophin gene exon deletion that does not result in a frame shift error. The downstream exons are still translated and the resultant protein, although altered, still has some normal func-

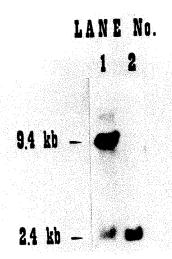

Fig. 2. Southern blot of genomic DNA digested with *Eco*RI restriction endonuclease. Hybridization with probe hAR1 reveals absent band in affected patient (*lane 2*) versus control in *lane 1*.

tion. Hence Becker muscular dystrophy is a much less severe disease. 15, 16

The published sequence of the entire androgen receptor gene? indicates that complete deletions of either exon 3 or 4 will not result in a frameshift error of the exons downstream. However, deletions of any of the other exons will result in a frameshift error that would be manifested at the time of translation. These observations further support our findings of a deleted exon 4 in an azoospermic male. Exons 5 to 8, which make up the bulk of the steroid-binding domain, 7. 12 would thus be intact and available for proper translation allowing for the male phenotype. However, as discussed previously, the amount of receptor-steroid complex reaching the target cell nucleus may be decreased and inadequate for spermatogenesis. Future study of this patient in question may be further revealing.

LETTERS TO THE EDITORS

Giacomello's observation and nuchal cords

To the Editors: In Giacomello's letter (Giacomello F. Ultrasound determination of nuchal cord in breech presentation. Am J OBSTET GYNECOL 1988;159:531-2) a description of an umbilical cord pattern relative to the fetal neck was illustrated. Giacomello warned that before initiating version on a breech fetus physicians should be aware of the possibility of nuchal cord tightening. He did not mention the quantitation of this pattern. Patterns A and B were studied in 288 deliveries. Careful attention was paid to the cross-over versus cross-under forms. Thirty-nine nuchal cords were delineated, and all crossed over the umbilical end (pattern A). Although a cross-under form (pattern B) was not observed, it is the only pattern that can create a true knot. That there were 11 true knots in this series suggests that pattern A is more common than pattern B and that fetal rotation on its long axis (360 degrees) is the predominant mechanism of nuchal cords; however, it does not suggest that pattern B does not exist in the form of a nuchal cord even though pattern B was not observed in this series.

Reply

To the Editors: We are grateful for the opportunity to reply to the interesting comments regarding our letter. Collins reports his data on 288 deliveries concerning the incidence of umbilical cord knots and of the nuchal cord patterns shown in Fig. 1 accompanying our letter. Although pattern B was not recorded, pattern A and true knots were observed in 39 (13.5%) and 11 (3.8%) cases, respectively. The incidence of cord knots has been reported to be from 0.3% to 2.1% and that of encirclements from 15.8% to 30%, but a wider range is possible, especially in small series. Recently, two consecutive cases of midtrimester abortion occurring at 16 and 18 weeks' gestation in association with cord encirclement of the fetal neck were recorded in our institution; in the second case pattern B was observed. In our letter the pattern of cord encirclement was not recorded because our observations did not focus on this issue. We agree with Collins, whose data suggested that "fetal rotation on its long axis (360 degrees) is the predominant mechanism of nuchal cords." On the other hand, pattern B can be considered to be an incomplete knot; its rarity at birth could support the common belief that cord knotting occurs within the first trimester because of the peculiar proportion of the small fetus (big head compared with the body) moving in a relatively large amount of amniotic fluid. In addition, pattern B is more dangerous for the fetus than a complete knot because the cord can tighten very easily

and lead to fetal miscarriage in the second trimester, as was observed in our second case.

We have not suggested that nuchal cord tightening during external cephalic version could be related to pattern B. Other factors such as a short cord or multiple encirclements could be involved. The interesting point was that in breech delivery pattern B, even if uncommon, tightens and pattern A may easily unroll and not be recorded at birth. However, in cephalic presentation intrauterine cord encirclements of the fetal neck are usually recorded at birth, at least with normal fetal rotation.

The increased safety and success rate of external cephalic version can be attributed, at least in part, to correct patient selection on the basis of clinical and ultrasonographic data and fetal heart rate monitoring. The ultrasonographic evidence of multiple nuchal cords and neck hyperextension could advise against too vigorous attempts at cephalic version to avoid complications.

Ethics in medical studies with human subjects

To the Editors: We read with interest the recent article by Goldstein et al. (Goldstein I, Zimmer EZ, Merzbach D, Peretz BA, Paldi E. Intraamniotic infection in the very early phase of the second trimester. Am J Obstet Gynecol 1990;163:1261-3) in which they concluded that intraamniotic infection may exist early in a pregnancy with intact membranes. The findings of this and similar studies are fascinating and may shed light on the causes of otherwise unexplained spontaneous abortions or preterm contractions.

However, the results as described with evidence of a 50% perinatal complication rate (preterm delivery and septic abortion) do not in our minds represent a "relatively good outcome" and lead to these questions:

- 1. Was this study authorized or reviewed by an institutional ethics committee?
- 2. Were the patients aware that amniotic fluid cultures were obtained?
- 3. Did the patients give their consent before participating in the study?
- 4. In the cases with positive cultures, were the patients or attending physicians informed of the findings and consulted as to management; that is, was it considered that infection caused by pathogenic organisms such as *Klebsiella* and *Escherichia coli* or group B β -hemolytic streptococcus might be treated with antibiotic regimens?

In this day of active patient involvement in medical care and the current medicolegal atmosphere, these ethical issues are essential; if they were addressed by the authors, it was not clearly stated in the text.

David M. Sherer, MD, and Jacques S. Abramowicz, MD Division of Maternal-Fetal Medicine, Department of Obstetrics and Gynecology, Strong Memorial Hospital, The University of Rochester School of Medicine and Dentistry, 601 Elmwood Ave., Box 668, Rochester, NY 14642

Reply

To the Editors: We thank Sherer and Abramowicz for their interest in our study. The study was approved, patients' consent was obtained before amniocentesis, and patients were aware that amniotic fluid cultures were obtained. We are unaware of similar studies at such an early gestational age; to the best of our knowledge there are no data available as to how these cases should be treated. Patients were monitored in our outpatient clinic but were not treated with antibiotics. On the basis of the data obtained from our initial study, we are designing a new study in which patients with positive cultures will be offered treatment with antibiotics. The mode and duration of treatment and the possible need for a second amniocentesis after completion of treatment have still to be evaluated.

Factors affecting embryo implantation after human in vitro fertilization

To the Editors: Paulson et al. (Paulson RJ, Sauer MV, Lobo RA. Factors affecting embryo implantation after human in vitro fertilization: a hypothesis. Am J Obstet Gynecol 1990;163:2020-3) present a model for attempting to define some very difficult questions regarding oocyte-embryo quality and endometrial receptivity in in vitro fertilization (IVF). I take issue with their use of the model and some of the conclusions derived from it.

In comparing their oocyte donation and regular IVF results, they made a relatively small number of observations to obtain the percentages of implantation for each group. If the 95% confidence limits were given for each of these, the reader would realize the very wide ranges within which the true values could lie based on the *n* of the samples used. These inaccuracies could profoundly influence the difference between the two rates, which was the basis for the estimation that receptivity is reduced during stimulated cycles by 67%. For example, if the two rates were 25% and 15%, receptivity would be reduced by only 40%.

The authors used the difference between these two implantation rates to conclude that endometrial receptivity is dramatically reduced in the stimulated cycle. Their conclusion is based on the critical assumption that egg quality was equal in the two groups. However, the egg donors were normal women. If they were younger

(mean ages were not given) or inherently more fertile than the women needing IVF, their oocyte quality could have been unusually high relative to that of the women needing IVF. Unless all of the IVF women had tubal occlusion from the beginning of their attempts at fertility, they could represent a subgroup of women who because of ovarian or uterine factors are less fertile than the total population of women with tubal disease who attempt pregnancy. The markedly reduced implantation of frozen donor oocytes compared with frozen oocytes from IVF patients also clearly indicates that either oocyte or uterine factors are present in the IVF population.¹

The reduction of the implantation rate in the IVF women could be caused by uterine factors other than the excess stimulation of the endometrium. These women differed from the egg recipients by having had pelvic infection. For example, implantation has been shown to be lower in women with positive titers for chlamydia.² The likelihood of the reduction being entirely caused by stimulation is certainly lessened by the authors' observation that implantation was increased with a greater level of stimulation.

The model proposed is a reasonable one to use in trying to define these difficult questions. However, the magnitude and cause of the reduced implantation in women having IVF remain to be defined.

Reply

To the Editors: In our December 1990 article we presented a formula that attempts to combine available embryo implantation information in a single expression: Embryo implantation rate (EI) = Embryo quality (EQ) × Endometrial receptivity (ER) × Transfer efficiency (TE). This formula allows comparison of any of the three variables (EQ, ER, or TE) among various assisted reproductive techniques. For example, TE may be different if embryos are replaced via fallopian tubes rather than transcervically, ER may be different with different endometrial stimulation regimens, etc. To formulate specific comparisons among different reproductive techniques, the standard algebraic problem of how to obtain values for each variable in equations with multiple independent variables must be solved. The solution is to have as many equations as there are independent variables. This works perfectly in the perfect world of mathematics but only imperfectly in the world of clinical medicine, where no quantitative comparisons are possible unless basic assumptions are made.

For the purpose of the Comment in our article, we assumed that EQ was equal in the donor and standard IVF groups; this is the assumption with which Dr. Meldrum takes issue. His point is well taken; although the groups were as similar as possible, they are technically not equivalent for the reasons he cites. The cohort of patients selected for the standard IVF group performs the best in our hands of all groups of IVF patients, but it may be possible that normal fertile women (who act as oocyte donors but otherwise have no reason to undergo IVF) would perform even better. Thus EQ might be higher in the donor group, and the observed decrease in implantation rates might not be entirely caused by decreased ER in the standard IVF group. We tend to believe that this is not the case and have elaborated on the matching of the two groups more extensively in the original report of those data. A better study design was actually reported by Levran et al.2 who divided embryos produced from a single cohort of oocytes among the donors themselves and two or more recipients. In their series, 12 oocyte aspirations led to 12 donor and 27 recipient embryo transfer procedures. Ten pregnancies resulted, all in the recipients and none in the donors, supporting the contention that (1) the quality of embryos derived in vitro from stimulated cycles is very high, with nearly all oocyte cohorts resulting in pregnancies, and (2) the endometria of patients who undergo controlled ovarian hyperstimulation are less receptive than those of patients who cycle naturally or have exogenously generated cycles.

To further delineate the magnitude of the effect of controlled ovarian hyperstimulation on ER, Dr. Meldrum points out the relatively small numbers of patients in our series. Indeed, these are the 95% confidence intervals, as determined by binomial expansion of EI for the two groups: Donor IVF (n = 75), EI = 35% (95% confidence interval = 24% to 46%); Standard IVF (n = 225), EI = 11% (95% confidence interval = 7% to 15%).

Thus, if we take the low extreme for the donors and the high extreme for the standard group (24% vs 15%), the magnitude of the reduction in ER is smaller (40%) than the 67% calculated on the basis of the observed EI rates. However, by the same argument, if the opposite extremes are used (46% vs 7%), a much higher ER effect (85%) can be calculated. We agree with Dr. Meldrum that the exact magnitude of the reduction in ER cannot be obtained from a single report, especially if this effect is different for different populations, but we believe that the value of 67% is a close approximation.

Finally, Dr. Meldrum quotes our observation³ that very high estradiol levels by themselves are not detrimental to the clinical outcome of IVF. This does not disprove the theory that controlled ovarian hyperstimulation is inhibitory to ER, however. There are many

other factors associated with high estradiol levels, including favorable patient selection (more fertile patients have higher estradiol responses) and greater ability to select embryos. There are other ovarian secretory products associated with controlled ovarian hyperstimulation that may not correlate with estradiol levels; thus inhibition of ER may not correlate with estradiol levels. Our article³ discusses these issues and states only that it is unlikely that the ER effect is mediated by estradiol alone.

We appreciate the opportunity to expound on our model and hope that our formulation will help others explain some of the differences among EI rates that they observe in their own programs. In this way we hope that greater insight may be gained into the process of embryo implantation and energy may be focused on appropriate parts of the puzzle. As of this point we feel that among younger IVF patients ER is the rate-limiting step of success and that if ER can be improved IVF pregnancy rates can be subtantially increased to approximate those of oocyte donation.

The origin of brain lesions in survivors of twin gestations complicated by fetal death

To the Editors: In their excellent study Bejar et al. (Bejar R, Vigliocco G, Gramajo H, et al. Antenatal origin of neurologic damage in newborn infants. II. Multiple gestations. Am J Obstet Gynecol 1990;162:1230-6) have found a high incidence (30%) of antenatal necrosis of the cerebral white matter in the survivors of monochorionic multiple gestations complicated by fetal death. On the basis of their findings and previous studies, the authors attribute those lesions to thromboemboli from the dead fetus reaching the surviving twin through the placental vascular anastomosis.

Although such a mechanism cannot be ruled out, a cause-and-effect association between the two has never been proved. Other possible explanations as to the high incidence of brain lesions in the survivors include (1) hypoxia and hypotension at the time of the insult that produced the single fetal death and (2) prematurity as a consequence of spontaneous or elective preterm delivery. We' recently reported the outcome of four mon-

ochorionic triplet gestations complicated by fetal death. No evidence for thromboembolic lesions was found in the nine survivors, and their outcome did not differ from that of a control group. In fact, the data presented by Bejar et al. hardly support the thromboembolic theory: Of the 12 monochorionic infants with antenatal necrosis of the cerebral white matter, in eight the lesions were present in both infants, in two only one infant was affected, and in two there was a history of a cotwin dying in utero. On the contrary, their data show that monochorionic placentation per se and not a dead fetus may be responsible for the high incidence of whitematter brain lesions (10/12 cases); the data certainly do not support any cause-and-effect relationship between fetal death and brain lesions in the survivors.

The clinical implication of this discussion is that fetal death in multiple gestation should not be considered an indication for delivery of the surviving fetus on the basis of the assumption that prompt delivery may prevent the development of vascular disruption, which could lead to disease in various organ systems. However, because the factor responsible for the death of one fetus may further jeopardize the survivor, close assessment of fetal well-being is mandatory.

Response declined

First report: Prenatal diagnosis of a true knot

To the Editors: A true knot of the umbilical cord occurs in approximately 1% of deliveries and leads to a peri-

natal loss of approximately 6%. To date, no published case of a prenatally diagnosed true knot could be located. Fig. 1 is a photograph of a true knot diagnosed at 32 weeks with a model 3000 General Electric ultrasonography unit. This 32-year-old woman, gravida 5, para 2, aborta 2, was evaluated with biweekly nonstress tests. By 36 weeks the fetal heart rate baseline rose from 160 to 180 beats/min. Repeat ultrasonography demonstrated decreased amniotic fluid. A follow-up oxytocin stress test elicited fetal heart rate decelerations. At planned cesarean section a viable male infant was delivered, with Apgar scores of 8 and 9 without meconium and an umbilical cord blood pH of 7.3. A characteristic feature of the sonogram photograph is the cloverleaf pattern of the true knot (Fig. 1). The diagnosis of a true knot in utero is possible. Prenatal management of such a finding should follow current established obstetric methods, which include fetal profile studies of Manning et al.1 and the fetal movement studies of Moore and Piacquadio.2

The effect of amnioinfusion on uterine pressure and activity

To the Editors: I read with some misgiving the article by Posner et al. (Posner MD, Ballagh SA, Paul RH. The effect of amnioinfusion on uterine pressure and activ-

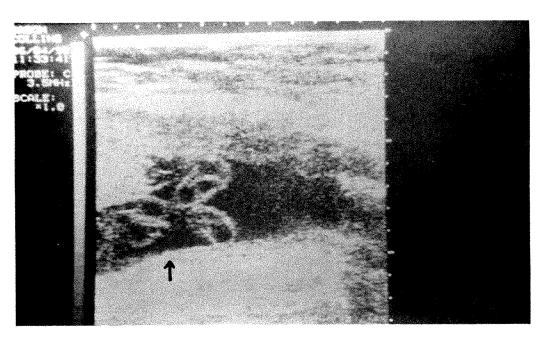

Fig. 1. Cloverleaf pattern of a true knot shown by arrow.

ity: A preliminary report. Am J OBSTET GYNECOL 1990;163:813-8). The authors noted a significant increase in uterine tone caused by amnioinfusion in 10 patients. In their Fig. 5 the uterine resting tone increased from 3 mm Hg to 33 mm Hg about ½ to 1 minute after the start of amnioinfusion; Posner et al. assumed a cause-and effect relationship. They ignored an increase in oxytocin (Pitocin) augmentation 6 minutes previously. Isn't the more logical cause simple oxytocin hyperstimulation? It would seem wise to exclude patients who are receiving oxytocin augmentation so that the uterotonic effects of oxytocin would not be confused with those of amnioinfusion.

Fred S. Miyazaki, MD

Southern California Permanente, Medical Group, 4900 Sunset Blvd., Los Angeles, CA 90027

Reply

To the Editors: We thank Miyazaki for his interest in our article. As he points out, oxytocin was infusing before the amnioinfusion. However, the dosage was not increased immediately before the beginning of the amnioinfusion; the dosage was simply written on the monitor strip at that time.

As part of our protocol oxytocin was allowed to be infused, but the dosage was not increased for a minimum of 60 minutes before the amnioinfusion. We included this as part of our protocol to control for the potential problem of uterine hyperstimulation. Because each patient was monitored for a 20-minute "steady-state" period before the amnioinfusion, this time period also included maintaining the oxytocin infusion at a constant dosage to prevent potential confounding clinical uterine hypersimulation.

We therefore believe that this event was real; even without including this patient in our calculations our results show a statistically significant increased uterine tone during and after amnioinfusion. We have been unable to identify those patients at risk for a hypertonic event; however, we continue to look into the problem.

Cesareans are more than skin deep

To the Editors: Use of the Allis test as proposed by Finan et al. (Finan MA, Mastrogiannis DS, Spellacy WN. The Allis test for easy cesarean delivery. Am J OBSTET GYNECOL 1991;164:772-5) to assure a skin incision that is approximately 15 cm in length will often result in an incision longer than that actually needed; even worse, the Allis test is no guarantee of an easy cesarean delivery.

The report does not mention having an adequate uterine incision and the techniques of assuring same. It also does not discuss differences found at the time of a primary cesarean as compared with the scarring and concretelike tissues that may be found in repeat

adhesions and adherent bowel loops. A vertical incision may be easily extended; however, the futility of extending the skin incision of a Pfannenstiel incision and the utility of cutting the muscles or detaching them from their insertion to obtain greater exposure when needed are not discussed.

A novice reading the report would get false assurance that a skin incision 15 cm long will assure easy cesarean delivery (when that is not the case) and would learn none of the measures that must be implemented when the predicted easy cesarean delivery becomes oh so difficult.

I also wonder how so many women still manage to deliver vaginally successfully when the hiatus in question is <15 cm. Perhaps adding advice about skills in addition to size would be a better predictor of easy cesarean delivery.

Sylvain Fribourg, MD

Letters 1899

13652 Cantara St., Panorama City, CA 91402

Reply

To the Editors: We thank Fribourg for the comments regarding our manuscript. The Allis test was not intended to be a gauge for skin incision length. As shown in Fig. 1 of our article, the Allis test is an objective means of measuring the distensibility of the entire anterior abdominal wall opening.

The size of the uterine incision was not measured in our report. Because we frequently extend the uterine incision with the operator's fingers, we have not found uterine incision size to be a frequent cause of dystocia at cesarean delivery.

The Allis test does objectively measure the distensibility of the skin incision, muscular defect, and fascial opening; thus it is a rough gauge of distensibility. It would indirectly reflect the concretelike tissues that Fribourg describes. The less elastic the tissue, the greater the incision size would have to be to pass the Allis test.

We have not found intraperitoneal adhesions and adherent bowel loops to be a cause of dystocia at cesarean delivery. These factors may occasionally cause difficulty with exposure. In our experience, as soon as the lower uterine segment is exposed, these factors do not restrict delivery. Because the objective gauge of delivery was the number of seconds from *uterine incision* to delivery, adhesions or adherent bowel loops would not have lengthened this time.

A grade IV difficult delivery was defined as "extension of the incision or muscle splitting" required to effect delivery. Incision of the rectus muscles in a transverse fashion (Maylard) may be required in a grade IV delivery. Detaching the rectus muscle from its insertion in the symphysis would certainly be another means of accomplishing this.

Finally, the question about successfully delivering vaginally when the cervix and vagina are not 15 cm dilated is a moot one. We doubt that the surgeons want a 1-hour second stage at cesarean section!

Table I. Ectopic pregnancy ranking of contraceptive methods: Circa 1980 to 1985

Alternative estimates of ectopic pregnancy risks during contraception

To the Editors: Franks et al. (Franks AL, Beral V, Cates W Jr, Hogue CJR. Contraception and ectopic pregnancy risk. Am J Obstet Gynecol 1990;163:1120-3) state that "differences in magnitude of ectopic pregnancy risk between contraceptives are so large that we believe the relative ranking of risk to be correct." The "typical" pregnancy rates of Trussell et al.¹ produce a different ranking of risk, however, for the United States in the early 1980s, as is shown in Table I. Conditional probabilities in Table I for U.S. copper intrauterine contraceptive devices (IUDs) are taken from Sivin and Stern,² and the proportion of pregnancies that were ectopic in the early 1980s are taken from Atrash.³

The typical pregnancy rates are for the first year of contraceptive use. Their division by a factor of three would bring the rates down to levels experienced by long-term users and also close to the values given as the lowest expected but would not change the rank order of the typical ectopic pregnancy rate.

Women using steroid-releasing IUDs have distinctly higher proportions of ectopic pregnancy (16% to 28%⁴) than the 4% found in copper IUD users² and have total ectopic pregnancy risks that overlap those of women who use no contraception (3.2 to 8.4 per 1000).

Very low risks of ectopic pregnancy among users of combined oral contraceptives may have increased since the early 1970s because of recent reformulations represented by triphasics and low estrogen dose.

Last, Franks et al. have not acknowledged prior similar approaches to estimation of ectopic pregnancy rates for women who use oral contraceptives, tubal sterilization, or IUDs, and for women who do not use contraceptive devices. Indeed, the same Hutterite fertility data cited by Franks et al. also served to estimate ectopic pregnancy rates for U.S. women not using contraceptive devices circa 1977 and for the period 1972 to 1976. The estimate of 2.6 ectopic pregnancies per 1000 U.S. women not using contraceptive devices in the early 1970s by Franks et al. is 90% of the value published in 1989 by Sivin. Virtually identical approaches yield virtually identical estimates of ectopic pregnancy rates in the United States in the early 1970s.

Irving Sivin, MA

Center for Biomedical Research, The Population Council, 1230 York Ave., New York, NY 10021

Reply

To the Editors: We appreciate Sivin's letter regarding our article. We find his calculations reassuring because they illustrate the utility of the method with a wide variety of assumptions. In spite of his using estimates for different time periods, a different type of contraceptive failure rate, and data from copper-containing IUDs rather than unmedicated IUDs, his results agree with our conclusions—that the use of no contraception carries the highest risk of ectopic pregnancy and that the use of oral contraceptives and vasectomy carry the lowest risk of ectopic pregnancy. We are pleased that his estimate of the rate of ectopic pregnancy for users of the newer copper-containing IUDs has a lower ranking of risk than we had calculated for the older, non-medicated IUDs.

We share Sivin's concern that risk of ectopic pregnancy may change when contraceptive methods are modified. It is imperative that accurate information be gathered on new contraceptives and on old ones that are reformulated. We believe that the approach we propose for estimating ectopic pregnancy risk will remain useful as new information becomes available.

First report: Prenatal diagnosis of long cord

To the Editors: Leonardo da Vinci observed that the umbilical cord is as long as the fetus at any given age. This is reasonably correct at >10 weeks' gestational age; by 28 weeks' gestation the umbilical cord length is essentially achieved. Cord growth continues until term but is minimized by 32 weeks. Correlations to umbilical cord length include fetal movement, nutritional status, and congenital anomalies. Unfortunately no reports of umbilical cord length could be located as determined by prenatal ultrasonography.2 This seems important for no better reason than the relationship between cord length and umbilical cord complications. A long cord is predisposed to a true knot formation and nuchal cord formation.3 Because of this it seems reasonable to measure cord length, and 28 weeks' gestation seems a reasonable time to do so. With an ultrasonography unit (GE 3200, GE Medical Systems, Milwaukee) 30 pregnancies were screened at 28 weeks specifically for long cord formation. With the trace mechanism the cord was

followed as closely as possible and length estimated. A cord >50 cm at 28 weeks was identified in 1 of the 30 fetuses. A long cord measuring 100 cm was confirmed at delivery. It may not be necessary to have an exact length measurement at term. The 28-week measurement may be the best possible estimate. Once these fetuses are identified, watching them for umbilical cord complications may be worthwhile.

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the American Journal of Obstetrics and Gynecology

The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is \$64.50 (\$69.00 international). Prices include shipping. Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.

Contact Mosby-Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318 USA; phone (314) 453-4394. In the U.S., call toll-free: 1-800-325-4177, ext. 4394. Please allow six weeks for delivery.

Abortion, animal

A rabbit model for bacterially induced preterm pregnancy loss: intervention studies with ampicillin-sulbactam (McDuffie et al). 1991;165:1568-74

Abortion, habitual

Anticomplementary activity in serum and abortion (Ergüven et al). 1991;165:1160-1 (Letter)

The prevalence of recurrent spontaneous abortions, cancer, and congenital anomalies in the families of couples with recurrent spontaneous abortions or gestational trophoblastic tumors (Ho et al). 1991;165:461-6

Subchorionic hematomas and the presence of autoantibodies (Baxi and Pearlstone). 1991;165:1423-4

Abortion, septic

A life-threatening sexually transmitted *Haemophilus influenzae* in septic abortion: a case report (Pinhas-Hamiel et al). 1991;165:66

Abortion, therapeutic

Acute myocardial infarction associated with prostaglandin E₂ (Meyer et al). 1991;165:359-60

Abortion, threatened

Predictive value of early embryonic cardiac activity for pregnancy outcome (Merchiers et al). 1991;165:11-

Abruptio placentae

Recurrent mild abruptio placentae occurring immediately after repeated electroconvulsive therapy in pregnancy (Sherer et al). 1991;165:652-3

On reducing the frequency of severe abruptio placentae (Pritchard et al). 1991;165:1345-51

Acanthosis nigricans

Polycystic ovary syndrome and the androgen-insulin connection (Nader). 1991;165:346-8 (Clin. opinion)

Acid-base equilibrium

Amnioinfusion increases amniotic pressure in pregnant sheep but does not alter fetal acid-base status (Fisk et al). 1991;165:1459-63

Acoustic stimulation

Effects of vibration frequency and tissue thickness on intrauterine sound levels in sheep (Richards et al). 1991:165:438-42

Fetal heart rate response to vibroacoustic stimulation during low and high heart rate variability episodes in late pregnancy (Spencer et al). 1991;165:86-90

Adenoma

A case report of prostaglandin E₂ termination of pregnancy complicated by Cushing's syndrome (Buescher et al). 1991;165:1412-3

Adenomyosis; see Endometriosis

Adenosine cyclic monophosphate

Regulation of corticotropin responsiveness in human fetal adrenal cells (Rainey et al). 1991;165:1649-54

Adenosine triphosphate

Characterization of in vitro chemosensitivity of perioperative human ovarian malignancies by adenosine triphosphate chemosensitivity assay (Gerhardt et al). 1991;165:245-55

Adhesions

Resolution of chronic pelvic pain after laparoscopic lysis of adhesions (Steege and Stout). 1991;165:278-83

Adhesions, animal

- The ability of recombinant tissue plasminogen activator to inhibit post—radical pelvic surgery adhesions in the dog model (Montz et al). 1991;165:1539-42
- The effect of interleukin-1 on adhesion formation in the rat (Hershlag et al). 1991;165:771-4
- Reduction of primary posttraumatic adhesion formation with the prostacyclin analog iloprost in a rodent model (Steinleitner et al). 1991;165:1817-20

Adipose tissue

The cheek-to-cheek diameter in the ultrasonographic assessment of fetal growth (Abramowicz et al). 1991; 165:846-52

Adolescence

- Center for Research, Education, Service and Training's fertility education program for youth (Mascarenhas). 1991;165:2070 (Abstract)
- Fertility education for young men (Burke). 1991;165:2071 (Abstract)
- Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cohort (Klaus and Kardatzke). 1991;165:2071 (Abstract)

Adrenal cortex hormones

- Congenital heart block: successful prophylactic treatment with intravenous gamma globulin and corticosteroid therapy (Kaaja et al). 1991;165:1333-4
- The effects of betamethasone on maternal cellular resistance to infection (Cunningham and Evans). 1991; 165:610-5

Adrenal glands

Regulation of corticotropin responsiveness in human fetal adrenal cells (Rainey et al). 1991;165:1649-54

Adrenal glands, animal

The effect of hypothalamic lesions on the length of gestation in fetal sheep (Gluckman et al). 1991;165:1464-8

Adrenocorticotropic hormone

Regulation of corticotropin responsiveness in human fetal adrenal cells (Rainey et al). 1991;165:1649-54

Adult respiratory distress syndrome; see Respiratory distress syndrome, adult

Africa

- Client teaching materials for francophone Africa (Ecochard). 1991;165:2072 (Abstract)
- A management needs assessment for African natural family planning programs: process and results (Pedersen). 1991;165:2073 (Abstract)

Agency for International Development

Natural family planning: Agency for International Development policy considerations (Clark and Spieler). 1991;165:2074 (Abstract)

Airway resistance

Effect of cigarette smoking on maternal airway function during pregnancy (Das et al). 1991;165:675-9

Alcohol drinking

Identifying pregnant women who drink alcoholic beverages (Mullen et al). 1991;165:1429-30

Allis test

Cesareans are more than skin deep (Fribourg) (Letter); (Finan) (Reply). 1991;165:1899

Alpha fetoproteins

The effect of gestational age on the detection rate of Down's

- syndrome by maternal serum α-fetoprotein screening (Greenberg et al). 1991;165:1391-3
- Prospective evaluation of maternal serum human chorionic gonadotropin levels in 3428 pregnancies (Bogart et al). 1991;165:663-7
- Risk of open spina bifida (Hershey) (Letter); (Thornton) (Reply). 1991;165:1159
- Risks associated with an elevated maternal serum α-fetoprotein level (Crandall et al). 1991;165:581-6
- Value of high and low maternal serum α-fetoprotein levels in screening singleton pregnancies (Minaretzis and Tsionou) (Letter); (Milunsky) (Reply). 1991;165:780

Ambulatory care centers'.

An epidemic of antiabortion violence in the United States (Grimes et al). 1991;165:1263-8 (Clin. opinion)

Amino acids

Tryptophan and neutral amino acids in premenstrual syndrome (Rapkin et al). 1991;165:1830-3

Amino acids, branched chain

Does intensive glycemic control in diabetic pregnancies result in normalization of other metabolic fuels? (Reece et al). 1991;165:126-30

Amniocentesis

- Are choroid plexus cysts an indication for second-trimester amniocentesis? (Achiron and Mashiach) (Letter); (Benacerraf) (Reply). 1991;165:239-41
- Enhanced sensitization after cordocentesis in a rhesusisoimmunized pregnancy (MacGregor et al). 1991;165: 382-3
- Impact of prenatal testing on maternal-fetal bonding: chorionic villus sampling versus amniocentesis (Caccia et al). 1991;165:1122-5
- Single-center comparison of results of 1000 prenatal diagnoses with chorionic villus sampling and 1000 diagnoses with amniocentesis (Young et al). 1991;165:255-63
- Transcervical chorionic villus sampling and midtrimester oligohydramnios (Cheng et al). 1991;165:1063-8

Amnioinfusion; see Amniotic fluid

Amnion

Endothelin production by amnion and its regulation by cytokines (Mitchell et al). 1991;165:120-4

Amniotic fluid

- Amniotic fluid bilirubin and fetal hemolytic disease (Spinnato et al). 1991;165:1030-5
- Amniotic fluid contains tissue factor, a potent initiator of coagulation (Lockwood et al). 1991;165:1335-41
- Amniotic fluid white blood cell count: a rapid and simple test to diagnose microbial invasion of the amniotic cavity and predict preterm delivery (Romero et al). 1991;165:821-30
- Correlation of amniotic fluid glucose concentration and intraamniotic infection in patients with preterm labor or premature rupture of membranes (Gauthier et al). 1991;165:1105-10
- Correlation of amniotic fluid index and nonstress test in patients with preterm premature rupture of membranes (Harding et al). 1991;165:1088-94
- Do catechol estrogens participate in the initiation of labor? (Biswas et al). 1991;165:984-7
- Does amniotic fluid index affect the accuracy of estimated fetal weight in preterm premature rupture of membranes? (Toohey et al). 1991;165:1060-2
- The effect of amnioinfusion on uterine pressure and activity (Miyazaki) (Letter); (Posner) (Reply). 1991;165:1898-9
- Neutrophil attractant/activating peptide-1/interleukin-8 in

Amniotic fluid-cont'd

term and preterm parturition (Romero et al). 1991; 165:813-20

Prophylactic amnioinfusion as a treatment for oligohydramnios in laboring patients: a prospective, randomized trial (Schrimmer et al). 1991;165:972-5

A rapid visual test for predicting fetal lung maturity (Sbarra et al). 1991;165:1351-3

Variable decelerations in reactive nonstress tests with decreased amniotic fluid index predict fetal compromise (Hoskins et al). 1991;165:1094-8

: Amniotic fluid, animal

Amnioinfusion increases amniotic pressure in pregnant sheep but does not alter fetal acid-base status (Fisk et al). 1991;165:1459-63

Amniotic fluid volume response to esophageal occlusion in fetal sheep (Fujino et al). 1991;165:1620-6

Oral-nasal membranes are not the major route for fetal absorption of amniotic fluid arginine vasopressin (Gilbert et al). 1991;165:1614-20

Amphetamines

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-7

Ampicillin

A rabbit model for bacterially induced preterm pregnancy loss: intervention studies with ampicillin-sulbactam (McDuffie et al). 1991;165:1568-74

Anabolic steroids

Endocrine effects in female weight lifters who self-administer testosterone and anabolic steroids (Malarkey et al). 1991;165:1385-90

Androgens

Evidence for a partial deletion in the androgen receptor gene in a phenotypic male with azoospermia (Akin et al). 1991;165:1891-4

Is 11β-hydroxyandrostenedione a better marker of adrenal androgen excess than dehydroepiandrosterone sulfate? (Stanczyk et al). 1991;165:1839-42

Polycystic ovary syndrome and the androgen-insulin connection (Nader). 1991;165:346-8 (Clin. opinion)

Anemia

Hyporegenerative anemia associated with intrauterine transfusion in rhesus hemolytic disease (Thorp et al). 1991;165:79-81

Management of fetal hemolytic disease by cordocentesis. I. Prediction of fetal anemia (Weiner et al). 1991;165:546-53

Anemia, sickle cell

Antepartum fetal surveillance tests during sickle cell crisis (Anyaegbunam et al). 1991;165:1081-3

Anesthesia, local

Cesarean section by local anesthesia in patients with familial dysautonomia (Leiberman et al). 1991;165: 110-1

Aneuploidy

The association between fetal karyotype and mean corpuscular volume (Sipes et al). 1991;165:1371-6

Prospective evaluation of maternal serum human chorionic gonadotropin levels in 3428 pregnancies (Bogart et al). 1991;165:663-7

Angiotensin II

Angiotensin II vascular smooth-muscle receptors are not down-regulated in near-term pregnant sheep (Mackanjee et al). 1991;165:1641-8

Dose-dependent effects of angiotensin II on the ovine fetal cardiovascular system (Jones et al). 1991;165:1524-33

Effects of angiotensin II on atrial natriuretic peptide in pregnancy (Didden et al). 1991;165:692-5

Fetal and maternal plasma atrial natriuretic factor responses to angiotensin II infusion (Ross et al). 1991;165: 1635-41

Hemorrhage-induced reductions in plasma atrial natriuretic factor in the ovine fetus (Cheung and Brace). 1991;165:474-81

Left thoracic duct lymph flow responses to angiotensin II or atrial natriuretic factor infusion in the ovine fetus (Brace and Andres). 1991;165:1607-13

Anorexia

Infertility and eating disorders (McCluskey et al) (Letter); (Stewart) (Reply). 1991;165:1576-7

Anoxia

Hypertriglyceridemia in small-for-gestational-age fetuses (Bartnicki). 1991;165:1575 (Letter)

Anoxia, animal

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep (Arnold-Aldea et al). 1991;165:185-90

Antiabortion; see Abortion

Antibiotics

Adjunctive clindamycin therapy for preterm labor: results of a double-blind, placebo-controlled trial (McGregor et al). 1991;165:867-75

Antimicrobial therapy in preterm premature rupture of membranes: results of a prospective, double-blind, placebo-controlled trial of erythromycin (McGregor et al). 1991;165:632-40

Combination antibiotics and indomethacin in idiopathic preterm labor: a randomized double-blind clinical trial (Newton et al). 1991;165:1753-9

Effectiveness of antibiotic prophylaxis in preventing bacteriuria after multichannel urodynamic investigations: a blind, randomized study in 124 female patients (Baker et al). 1991;165:679-81

Antibodies

Anticardiolipin antibody-positive serum enhances endothelial cell platelet-activating factor production (Silver et al). 1991;165:1748-52

Lack of an association between late fetal death and antiphospholipid antibody measurements in the second trimester (Haddow et al). 1991;165:1308-12

Should anticardiolipin tests be performed in otherwise healthy pregnant women? (Harris and Spinnato). 1991;165:1272-7

Steroid therapy for hydrops associated with antibody-mediated congenital heart block (Watson and Katz). 1991;165:553-4

Subchorionic hematomas and the presence of autoantibodies (Baxi and Pearlstone). 1991;165:1423-4

Antibodies, monoclonal

New monoclonal antibodies identify the glycoprotein carrying the CA 125 epitope (O'Brien et al). 1991;165:1857-64

Anticancer drug sensitivity tests; see Drug screening assays, antitumor

Anticardiolipin antibody; see Antibodies

Anticoagulants

Administration of heparin by subcutaneous infusion with a programmable pump (Floyd et al). 1991;165:931-3

Antidiuretic hormone; see Vasopressins

Antifungal agents

The in vitro activity of terconazole against yeasts: its topical long-acting therapeutic efficacy in experimental vaginal candidiasis in rats (Van Cutsem). 1991;165:1200-6

Mode of action of anti-Candida drugs: focus on terconazole and other ergosterol biosynthesis inhibitors (Vanden Bossche and Marichal). 1991;165:1193-9

Mycotic vulvovaginitis: a broad overview (Horowitz). 1991;165:1188-92

Vulvovaginitis: the role of patient compliance in treatment success (Nixon). 1991;165:1207-9

Antigens, differentiation

Expression of cytokine receptors and markers of differentiation in human papillomavirus—infected cervical tissues (McGlennen et al). 1991;165:696-705

Antigens, tumor-associated, carbohydrate

CA 125 in breast milk (Fuith) (Letter); (O'Brien) (Reply). 1991;165:1158-9

CA 125 regression: a model for epithelial ovarian cancer response (Buller et al). 1991;165:360-7

An extraordinarily high CA 125 level in a woman without apparent pathologic foci of CA 125 production: dissociation between serum levels of CA 125 and CA 130 (Kobayashi et al). 1991;165:1297-9

Increased serum levels of macrophage colony-stimulating factor in ovarian cancer (Xu et al). 1991;165:1356-62

New monoclonal antibodies identify the glycoprotein carrying the CA 125 epitope (O'Brien et al). 1991;165:1857-64

Prognostic value of CA 125 and neopterin in women with ovarian cancer undergoing second-look laparotomy (Fuith et al). 1991;165:779 (Letter)

Secondary müllerian system and endometriosis (Fujii). 1991;165:219-25 (Symposium)

Severe ovarian hyperstimulation in a spontaneous singleton pregnancy (Rosen and Lew). 1991;165:1312-3

Antihypertensive agents

Concentration of digoxin-like immunoreactive substance in patients with preeclampsia and its relation to severity of pregnancy-induced hypertension (Kaminski and Rechberger). 1991;165:733-6

Indomethacin induces hypertensive crisis in preeclampsia irrespective of prior antihypertensive drug therapy (Mousavy) (Letter); (Schoenfeld) (Reply). 1991;165:1577

Antioxidants

Antioxidant systems in normal pregnancy and in pregnancy-induced hypertension (Wisdom et al). 1991;165: 1701-4

Aorta

Pulmonary-to-aorta diameter ratio in the normal and abnormal fetal heart (Comstock et al). 1991;165:1038-44

Appendectomy

Incidental appendectomy during videolaseroscopy (Nezhat and Nezhat). 1991;165:559-64

Aprotinin

Aprotinin blocks the binding of pro atrial natriuretic peptides 1 to 30, 31 to 67, and 99 to 126 in human placental membranes (Vesely). 1991;165:567-73

Arachidonic acids

The effect of the menstrual cycle and of decompression stress on arachidonic acid—induced platelet aggregation and on intrinsic platelet thromboxane production in women compared with men (Markham et al). 1991; 165:1821-9

Arginine vasopressin; see Argipressin

Argipressin

Hemorrhage-induced reductions in plasma atrial natriuretic factor in the ovine fetus (Cheung and Brace). 1991;165:474-81

Oral-nasal membranes are not the major route for fetal absorption of amniotic fluid arginine vasopressin (Gilbert et al). 1991;165:1614-20

Ascites

Prolonged clearance of intraperitoneal 16α -[125]Ijiodo-17 β -estradiol in presence of ascites (Scharl et al). 1991; 165:1847-53

Asphyxia

"Meconiumcrit" and birth asphyxia (Trimmer and Gilstrap). 1991;165:1010-3

Asphyxia neonatorum

Neurologic versus behavioral neonatal assessment after birth asphyxia (Amiel-Tison and Stewart) (Letter); (Low) (Reply). 1991;165:1157

Aspirin

Transfer of aspirin across the perfused human placental cotyledon (Jacobson et al). 1991;165:939-44

Atrial natriuretic peptides; see Natriuretic peptides, atrial Atrophy

Postpartum vaginal atrophy (Wisniewski and Wilkinson). 1991;165:1249-54

Autoantibodies

The prevalence of autoantibodies during third-trimester pregnancy complicated by hypertension or idiopathic fetal growth retardation (Milliez et al). 1991;165:51-6

Subchorionic hematomas and the presence of autoantibodies (Baxi and Pearlstone). 1991;165:1423-4

Automated data processing

Automated management information systems (Nesbitt). 1991;165:2074 (Abstract)

Autosome abnormalities; see Chromosome abnormalities Azoospermia; see Oligospermia

В

Bacteria

A rabbit model for bacterially induced preterm pregnancy loss: intervention studies with ampicillin-sulbactam (McDuffie et al). 1991;165:1568-74

Bacteria, anaerobic

A new proline aminopeptidase assay for diagnosis of bacterial vaginosis (Schoonmaker et al). 1991;165: 737-42

Bacterial infections

Bacterial vaginosis: current review with indications for asymptomatic therapy (Thomason et al). 1991;165:1210-7

Cytolytic vaginosis (Cibley and Cibley). 1991;165:1245-9 Epidemiology of vaginitis (Kent). 1991;165:1168-76

Nonbarrier contraceptives and vaginitis and vaginosis (Roy). 1991;165:1240-4

Vulvar vestibulitis syndrome: an overview (Marinoff and Turner). 1991;165:1228-33

Bacteriuria

Effectiveness of antibiotic prophylaxis in preventing bacteriuria after multichannel urodynamic investigations: a blind, randomized study in 124 female patients (Baker et al). 1991;165:679-81

Barbiturates

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-

1934 Subject index December 1991
Am J Obstet Gynecol

Baroreflex

Baroreflex function in normal pregnancy (Leduc et al). 1991:165:886-90

Behavior

Neurologic versus behavioral neonatal assessment after birth asphyxia (Amiel-Tison and Stewart) (Letter); (Low) (Reply). 1991;165:1157

Bernard-Soulier syndrome

Obstetric complications in a patient with Bernard-Soulier syndrome (Peng et al). 1991;165:425-6

Betamethasone

The effects of betamethasone on maternal cellular resistance to infection (Cunningham and Evans). 1991; 165:610-5

Bilirubin

Amniotic fluid bilirubin and fetal hemolytic disease (Spinnato et al). 1991;165:1030-5

Binding sites

Specific binding sites for insulin and insulin-like growth factor I in human endometrial cancer (Nagamani et al). 1991;165:1865-71

Biometry

The relationship between umbilical artery Doppler velocimetry and fetal biometry (Scorza et al). 1991;165:1013-9

Biopsy

In utero fetal muscle biopsy for the diagnosis of Duchenne muscular dystrophy (Evans et al). 1991;165:728-32

Bipolar forceps; see Surgical instruments

Birth defects; see Abnormalities

Birth intervals

Breastfeeding: a natural method for child spacing (Howie). 1991;165:1990-1

Birth trauma; see Delivery, injuries Birth weight

Does amniotic fluid index affect the accuracy of estimated fetal weight in preterm premature rupture of membranes? (Toohey et al). 1991;165:1060-2

Intrapartum ultrasonographic estimates of fetal weight by the house staff (Platek et al). 1991;165:842-5

Psychosocial support for maternal stress during pregnancy: effect on birth weight (Rothberg and Lits). 1991;165:403-

Bladder

The role of prostaglandins in detrusor instability (Bergman et al). 1991;165:1833-6

Blastocyst

Partial dissection of the zona pellucida of frozen-thawed human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Bleeding; see Hemorrhage

Blood cell count

Amniotic fluid white blood cell count: a rapid and simple test to diagnose microbial invasion of the amniotic cavity and predict preterm delivery (Romero et al). 1991;165:821-30

Changes in immunologic parameters in normal pregnancy and spontaneous abortion (MacLean et al). 1991;165:890-

Blood coagulation

Amniotic fluid contains tissue factor, a potent initiator of coagulation (Lockwood et al). 1991;165:1335-41

Selective effects of preeclamptic sera on human endothelial cell procoagulant protein expression (Taylor et al). 1991;165:1705-10

Blood flow velocity

Arterial blood flow velocity waveforms of the pelvis and lower extremities in normal and growth-retarded fetuses (Mari). 1991;165:143-51

Does the brachial artery Doppler flow velocity waveform reflect changes in downstream impedance? (Fairlie and Walker). 1991;165:1741-4

Doppler flow velocities in single umbilical arteries (Duerbeck et al). 1991;165:1120-2

Fetal atrioventricular and outflow tract flow velocity waveforms during normal second half of pregnancy (van der Mooren et al). 1991;165:668-74

Fetal cardiac function in intrauterine growth retardation (Rizzo and Arduini). 1991;165:876-82

Maternal hemodynamics in pregnancy (Baumann and Huch) (Letter); (Ikeda and Mori) (Reply). 1991;165:237-8

Blood flow velocity, animal

Fetal hypertension induced by norepinephrine infusion and umbilical artery flow velocity waveforms in fetal sheep (van Huisseling et al). 1991;165:450-5

Blood gas analysis

Fetal blood sampling in patients undergoing elective cesarean section: a correlation with cord blood gas values obtained at delivery (Khoury et al). 1991;165:1026-9

Relationship between fetal biophysical activities and umbilical cord blood gas values (Vintzileos et al). 1991;165:707-

Blood glucose

Does intensive glycemic control in diabetic pregnancies result in normalization of other metabolic fuels? (Reece et al). 1991;165:126-30

Blood pressure

Baroreflex function in normal pregnancy (Leduc et al). 1991;165:886-90

Blood pressure, animal

Circadian rhythms of heart rate and mean arterial pressure in chronically instrumented pregnant rats (Melone et al). 1991;165:758-63

Dose-dependent effects of angiotensin II on the ovine fetal cardiovascular system (Jones et al). 1991;165: 1524-33

Enhanced endothelium-derived relaxing factor activity in pregnant, spontaneously hypertensive rats (Ahokas et al). 1991;165:801-7

Blood transfusion, intrauterine

Absence of hyperinsulinemia in isoimmunized fetuses treated with intravascular transfusion (Socol et al). 1991;165:1737-40

Atrial natriuretic peptide: A vasodilator of the fetoplacental circulation? (Kingdom et al). 1991;165:791-800

Bleeding after intravascular transfusion: experimental and clinical observations (Segal et al). 1991;165:1414-8

Hyporegenerative anemia associated with intrauterine transfusion in rhesus hemolytic disease (Thorp et al). 1991;165:79-81

Management of fetal hemolytic disease by cordocentesis. I. Prediction of fetal anemia (Weiner et al). 1991;165:546-

Management of fetal hemolytic disease by cordocentesis. II. Outcome of treatment (Weiner et al). 1991;165:1302-7

Porencephalic cyst: a complication of fetal intravascular transfusion (Dildy et al). 1991;165:76-8

Risk factors for cordocentesis and fetal intravascular transfusion (Weiner et al). 1991;165:1020-5

Blood volume

The association between fetal karyotype and mean corpuscular volume (Sipes et al). 1991;165:1371-6

Hemorrhage-induced reductions in plasma atrial natriuretic factor in the ovine fetus (Cheung and Brace). 1991;165:474-81

Blood volume, animal

Dose-dependent effects of angiotensin II on the ovine fetal cardiovascular system (Jones et al). 1991;165: 1524-33

Books

Books received. 1991;165:490-1, 1946-7

Brachial artery

Does the brachial artery Doppler flow velocity waveform reflect changes in downstream impedance? (Fairlie and Walker). 1991;165:1741-4

Bradycardia

Risk factors for cordocentesis and fetal intravascular transfusion (Weiner et al). 1991;165:1020-5

Steroid therapy for hydrops associated with antibody-mediated congenital heart block (Watson and Katz). 1991;165:553-4

Brain

The origin of brain lesions in survivors of twin gestations complicated by fetal death (Gonen). 1991;165:1897-8 (Letter)

Brain, blood supply, animal

In vivo and in vitro effects of magnesium sulfate in the cerebrovascular bed of the goat (Perales et al). 1991;165:1534-8

Brazil

Experiences in the field: Confederacao Nacional de Centros de Planejamento Natural da Familia, Brazil (Sogayar). 1991;165:2071 (Abstract)

Natural family planning through the health sector in Brazil (Sogayar). 1991;165:2073 (Abstract)

Breast diseases

Breast disease management in an obstetrics and gynecology department (Keramopoulos et al) (Letter); (Hall) (Reply). 1991;165:484-5

Breast feeding; see also Lactational amenorrhea

Breastfeeding: a natural method for child spacing (Howie). 1991;165:1990-1

CA 125 in breast milk (Fuith) (Letter); (O'Brien) (Reply). 1991;165:1158-9

Efficacy of the symptothermal method of natural family planning in lactating women after the return of menses (Zinaman and Stevenson). 1991;165:2037-9

Is the lactational amenorrhea method a part of natural family planning? Biology and policy (Gross). 1991;165:2014-9

The natural family planning-lactational amenorrhea method interface: observations from a prospective study of breastfeeding users of natural family planning (Kennedy et al). 1991;165:2020-6

Overview and summary: the interface of breastfeeding, natural family planning, and the lactational amenorrhea method (Labbok and Howie). 1991;165:2013-4

Ovulation method use during breastfeeding: Is there increased risk of unplanned pregnancy? (Labbok et al). 1991;165:2031-6

The promotion of exclusive breastfeeding and the lactational amenorrhea method in natural family planning programs (Kennedy). 1991;165:2076 (Abstract)

Santiago Breastfeeding Promotion Program: preliminary

results of an intervention study (Pérez and Valdés). 1991:165:2039-44

Ultrasonographic patterns of ovarian activity during breast-feeding (Flynn et al). 1991;165:2027-31

Breast neoplasms

Breast disease management in an obstetrics and gynecology department (Keramopoulos et al) (Letter); (Hall) (Reply). 1991;165:484-5

Breech presentation

External cephalic version after previous cesarean section (Flamm et al). 1991;165:370-2

Giacomello's observation and nuchal cords (Collins) (Letter); (Giacomello) (Reply). 1991;165:1895

Budgets

Budgeting and financial planning in natural family planning programs: in search of the perfect system (Pedersen). 1991;165:2074 (Abstract)

Rulimia

Infertility and eating disorders (McCluskey et al) (Letter); (Stewart) (Reply). 1991;165:1576-7

Cancer; see Neoplasms

Candida

Cytolytic vaginosis (Cibley and Cibley). 1991;165:1245-9 Mode of action of anti-Candida drugs: focus on terconazole and other ergosterol biosynthesis inhibitors (Vanden Bossche and Marichal). 1991;165:1193-9

Mycotic vulvovaginitis: a broad overview (Horowitz). 1991;165:1188-92

Candidiasis

Vulvar vestibulitis syndrome: an overview (Marinoff and Turner). 1991;165:1228-33

Candidiasis, vulvovaginal

Epidemiology of vaginitis (Kent). 1991;165:1168-76

Candidiasis, vulvovaginal, animal

Fungal morphology after treatment with itraconazole as a single oral dose in experimental vaginal candidosis in rats (Jansen et al). 1991;165:1552-7

The in vitro activity of terconazole against yeasts: its topical long-acting therapeutic efficacy in experimental vaginal candidiasis in rats (Van Cutsem). 1991;165:1200-6

Cannabis

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-7

Carbohydrates

Longitudinal changes in insulin release and insulin resistance in nonobese pregnant women (Catalano et al). 1991;165:1667-72

Carcinoma

Effects of peritoneal macrophages from patients with endometriosis on the proliferation of endometrial carcinoma cell line ECC-1 (Zhang et al). 1991;165:1842-6

A plea for early diagnosis of fallopian tube carcinoma: Can hysteroscopy be of use? (Sholapurkar). 1991;165:483 (Letter)

Primary invasive vaginal carcinoma (Eddy et al). 1991;165:292-8

Carcinoma, squamous cell

Human papillomavirus infection in women with multicen-

Carcinoma, squamous cell-cont'd

tric squamous cell neoplasia (Beckmann et al). 1991;165:1431-7

Vulvar squamous cell carcinoma and papillomaviruses: Two separate entities? (Andersen et al). 1991;165:329-36

Cardiolipins

Anticomplementary activity in serum and abortion (Ergüven et al). 1991;165:1160-1 (Letter)

Should anticardiolipin tests be performed in otherwise healthy pregnant women? (Harris and Spinnato). 1991;165:1272-7

Subchorionic hematomas and the presence of autoantibodies (Baxi and Pearlstone). 1991;165:1423-4

Cardiotocography

Extended longitudinal study of uterine activity among lowrisk women (Main et al). 1991;165:1317-22

Home monitoring of uterine contractility (Rhoads et al). 1991;165:2-6 (Clin. opinion)

Qualitative evaluation of uterine contractions recorded by a double guard-ring tocodynamometer (Shinmoto et al). 1991;165:1282-6

Severe obstructive sleep apnea and associated snoring documented during external tocography (Sherer et al). 1991;165:1300-1

Cardiovascular system

When do cardiovascular parameters return to their preconception values? (Capeless and Clapp). 1991;165: 883-6

Cardiovascular system, animal

Dose-dependent effects of angiotensin II on the ovine fetal cardiovascular system (Jones et al). 1991;165:1524-33

Fetal cardiovascular and fluid responses to maternal volume loading with lactated Ringer's or hypotonic solutions (Powers and Brace). 1991;165:1504-15

Role of endogenous atrial natriuretic factor in the regulation of fetal cardiovascular and renal function (Cheung). 1991;165:1558-67

Catechol estrogens

Do catechol estrogens participate in the initiation of labor? (Biswas et al). 1991;165:984-7

Catholicism

An American national experience: natural family planning serves under the auspices of the Roman Catholic Church (Notare). 1991;165:2073 (Abstract)

Natural family planning: national program development in Kenya (Wahome and Mwaulu). 1991;165:2073 (Abstract)

Cecum, animal

The effect of interleukin-1 on adhesion formation in the rat (Hershlag et al). 1991;165:771-4

Cell adhesion

Expression of extracellular matrix—degrading metalloproteinases by cultured human cytotrophoblast cells: effects of cell adhesion and immunopurification (Bischof et al). 1991;165:1791-801

Cell line

Expression and amplification of the HER-2/neu (c-erbB-2) protooncogene in epithelial ovarian tumors and cell lines (Tyson et al). 1991;165:640-6

Cells, cultured

Isolation and purification of microvascular endothelium from human decidual tissue in the late phase of pregnancy (Gallery et al). 1991;165:191-6

Cellular resistance to infection; see Immunity, natural Center for Research, Education, Service and Training

Center for Research, Education, Service and Training's fer-

tility education program for youth (Mascarenhas). 1991;165:2070 (Abstract)

Central nervous system

Neurologic versus behavioral neonatal assessment after birth asphyxia (Am:el-Tison and Stewart) (Letter); (Low) (Reply). 1991;165:1157

Central venous pressure; see Venous pressure Cerclage

Prognostic factors and complication rates for cervical cerclage: a review of 482 cases (Treadwell et al). 1991:165:555-8

Cerebellum

Transverse cerebellar diameter: a useful predictor of gestational age for fetuses with asymmetric growth retardation (Lee et al). 1991;165:1044-50

Cerebral arteries, animal

In vivo and in vitro effects of magnesium sulfate in the cerebrovascular bed of the goat (Perales et al). 1991;165:1534-8

Cerebral palsy

Appropriateness of intrapartum fetal heart rate management and risk cf cerebral palsy (Melone et al). 1991;165:272-7

Cervical cancer; see Cervix neoplasms

Cervical intraepithelial neoplasia; see Cervix neoplasms

Cervical ripening; see Labor stage, first

Cervix, physiology

Quantification of cervical change: relationship to preterm delivery in the multifetal gestation (Newman et al). 1991;165:264-71

Cervix diseases

High risk of human papillomavirus infection and cervical squamous intraepithelial lesions among women with symptomatic human immunodeficiency virus infection (Vermund et al). 1991;165:392-400

Cervix incompetence

Prognostic factors and complication rates for cervical cerclage: a review of 482 cases (Treadwell et al). 1991;165:555-8

Cervix mucus

Human cervical mucus: research update (Katz). 1991; 165:1984-6

Materials for the modified mucus method (Dorairaj). 1991; 165:2072 (Abstract)

The modified mucus method in India (Dorairaj). 1991; 165:2066-7

Natural family planning: looking ahead (Queenan and Moghissi). 1991;165:1979-80

Ultrasonographic patterns of ovarian activity during breastfeeding (Flynn et a.). 1991;165:2027-31

Cervix neoplasms

Adverse psychologic consequences of positive cytologic cervical screening (Lerman et al). 1991;165:658-62

The association between human papillomavirus deoxyribonucleic acid status and the results of cytologic rescreening tests in young, sexually active women (Moscicki et al). 1991;165:67-71

Combined interferon alfa and doxorubicin in the treatment of advanced cervical cancer (Welander et al). 1991; 165:284-91

Ten years after cryosurgical treatment of cervical intraepithelial neoplasia (Dræby-Kristiansen et al). 1991;165:43-

Cervix uteri

Maturation of the uterine cervix by repeated intracervical

Volume 165 Number 6, Part 1

instillation of prostaglandin E_2 (Milliez et al). 1991; 165:523-8

Cesarean section

- Cesarean section by local anesthesia in patients with familial dysautonomia (Leiberman et al). 1991;165:110-1
- Cesareans are more than skin deep (Fribourg) (Letter); (Finan) (Reply). 1991;165:1899
- Elective versus emergency cesarean hysterectomy cases in a residency program setting: a review of 129 cases from 1984 to 1988 (Gonsoulin et al). 1991;165:91-4
- External cephalic version after previous cesarean section (Flamm et al). 1991;165:370-2
- Fetal blood sampling in patients undergoing elective cesarean section: a correlation with cord blood gas values obtained at delivery (Khoury et al). 1991;165:1026-9
- The fetal-pelvic index: a method of identifying fetal-pelvic disproportion in women attempting vaginal birth after previous cesarean delivery (Thurnau et al). 1991;165: 353-8
- Funic reduction for the management of umbilical cord prolapse (Barrett). 1991;165:654-7
- Laparoelytrotomy: abdominal delivery without uterine incision (Işik and Gülmezoğlu). 1991;165:781 (Letter)
- A randomized, double-blind trial of prostaglandin E₂ gel for cervical ripening and meta-analysis (Owen et al). 1991;165:991-6
- Shoulder dystocia: Should the fetus weighing ≥4000 grams be delivered by cesarean section? (Langer et al). 1991;165:831-7
- Shoulder dystocia and birth trauma in gestational diabetes: a five-year experience (Keller et al). 1991;165:928-30
- What is a low-lying placenta? (Oppenheimer et al). 1991;165:1036-8

Chemosensitivity assay, antitumor; see see Drug screening assays, antitumor

Chemotherapy; see Drug therapy

Child abuse, sexual

Correlation between sexual abuse and somatization in women with somatic and nonsomatic chronic pelvic pain (Reiter et al). 1991;165:104-9

Child spacing; see Birth intervals Chlamydia trachomatis

- Comparative efficacy of clindamycin versus erythromycin in eradication of antenatal *Chlamydia trachomatis* (Alger and Lovchik). 1991;165:375-81
- Detection of *Chlamydia trachomatis* endocervical infection in asymptomatic and symptomatic women: comparison of deoxyribonucleic acid probe test with tissue culture (Yang et al). 1991;165:1444-53
- Increased inducibility of inflammatory mediators from peripheral blood mononuclear cells of women with salpingitis (Witkin et al). 1991;165:719-23

Cholecystectomy

Case report of laparoscopic cholecystectomy in the third trimester of pregnancy (Pucci and Seed). 1991;165:401-

Chorioamnionitis

- Microbiologic causes and neonatal outcomes associated with chorioamnion infection (Hillier et al). 1991;165:955-61
- Preterm premature rupture of membranes: detection of infection (Roussis et al). 1991;165:1099-104
- Systemic administration of interleukin-1 induces preterm parturition in mice (Romero et al). 1991;165:969-71

Choriocarcinoma

Genetic identification of pregnancies responsible for cho-

riocarcinomas after multiple pregnancies by restriction fragment length polymorphism analysis (Osada et al). 1991;165:682-8

Chorionic villi sampling

- In utero diagnosis of congenital varicella zoster virus infection by chorionic villus sampling and polymerase chain reaction (Isada et al). 1991;165:1727-30
- Impact of prenatal testing on maternal-fetal bonding: chorionic villus sampling versus amniocentesis (Caccia et al). 1991;165:1122-5
- Single-center comparison of results of 1000 prenatal diagnoses with chorionic villus sampling and 1000 diagnoses with amniocentesis (Young et al). 1991;165:255-63
- Transcervical chorionic villus sampling and midtrimester oligohydramnios (Cheng et al). 1991;165:1063-8

Choristoma

Peritoneal endometriosis: endometrial tissue implantation as its primary etiologic mechanism (Ishimaru and Masuzaki). 1991;165:210-4 (Symposium)

Choroid plexus

Are choroid plexus cysts an indication for second-trimester amniocentesis? (Achiron and Mashiach) (Letter); (Benacerraf) (Reply). 1991;165:239-41

Chromatids

Sister chromatid exchange frequency in directly prepared cytotrophoblasts: demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes (Shulman et al). 1991;165:1877-80

Chromosome abnormalities

- The association between fetal karyotype and mean corpuscular volume (Sipes et al). 1991;165:1371-6
- Hydrops fetalis in the McKusick-Kaufman syndrome: a case report (Rosen and Bocian). 1991;165:102-3
- The presence of the testicular determining sequence, SRY, in 46,XY females with gonadal dysgenesis (Swyer syndrome) (Behzadian et al). 1991;165:1887-90
- Recombinant 8 syndrome: the pool of Hispanic pericentric inversion 8 carriers expands numerically and geographically (Izquierdo et al). 1991;165:1419-22
- Study of 156 cases of polyhydramnios and congenital malformations in a series of 118,265 consecutive births (Stoll et al). 1991;165:586-90
- Value of high and low maternal serum α-fetoprotein levels in screening singleton pregnancies (Minaretzis and Tsionou) (Letter); (Milunsky) (Reply). 1991;165:780

Chromosome deletion

Evidence for a partial deletion in the androgen receptor gene in a phenotypic male with azoospermia (Akin et al). 1991;165:1891-4

Chromosomes, human, pair 8

Recombinant 8 syndrome: the pool of Hispanic pericentric inversion 8 carriers expands numerically and geographically (Izquierdo et al). 1991;165:1419-22

Chronic myeloid leukemia; see Leukemia, myeloid, chronic Cigarette smoking; see Smoking

Circadian rhythm

- Circadian myometrial and endocrine rhythms in the pregnant rhesus macaque: effects of constant light and timed melatonin infusion (Matsumoto et al). 1991;165:1777-84
- Circadian rhythms of heart rate and mean arterial pressure in chronically instrumented pregnant rats (Melone et al). 1991;165:758-63

Cleft lip

Pseudoprognathism—an auxiliary ultrasonographic sign for transvaginal ultrasonographic diagnosis of cleft lip

Cleft lip-cont'd

and palate in the early second trimester (Bronshtein et al). 1991;165:1314-6

Cleft palate

Pseudoprognathism—an auxiliary ultrasonographic sign for transvaginal ultrasonographic diagnosis of cleft lip and palate in the early second trimester (Bronshtein et al). 1991;165:1314-6

Clindamycin

Adjunctive clindamycin therapy for preterm labor: results of a double-blind, placebo-controlled trial (McGregor et al). 1991;165:867-75

Bacterial vaginosis: current review with indications for asymptomatic therapy (Thomason et al). 1991;165:1210-7

Comparative efficacy of clindamycin versus erythromycin in eradication of antenatal *Chlamydia trachomatis* (Alger and Lovchik). 1991;165:375-81

Clinical opinion

Clinical opinion. 1991;165:2-10, 346-52, 493-501, 1263-71 Clomiphene

Effect of clomiphene citrate treatment on endometrial estrogen and progesterone receptor induction in women (Fritz et al). 1991;165:177-85

Coagulation; see Blood coagulation

Cocaine

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-7

The effect of maternal cocaine use on the fetus: changes in antepartum fetal heart rate tracings (Tabor et al). 1991;165:1278-81

Effects of intravenous cocaine on reproductive function in the mated rabbit (Atlas and Wallach). 1991;165:1785-90

Incidence and prevalence of human immunodeficiency virus infection in a prenatal population undergoing routine voluntary human immunodeficiency virus screening, July 1987 to June 1990 (Lindsay et al). 1991;165:961-4

Thrombotic thrombocytopenic purpura first seen as massive vaginal necrosis (Gallup et al). 1991;165:413-5

Coelomic metaplasia; see Metaplasia

Colposcopy

Adverse psychologic consequences of positive cytologic cervical screening (Lerman et al). 1991;165:658-62

Communication

Communicating with developing country policymakers: the case for natural family planning (Murphy). 1991;165: 2075 (Abstract)

Innovative approaches from population communication services: implications for natural family planning (Lozaré). 1991;165:2070 (Abstract)

Competence; see Professional competence

Complement fixation tests

Anticomplementary activity in serum and abortion (Ergüven et al). 1991;165:1160-1 (Letter)

Computer systems

The three most common occupational exposures reported by pregnant women: an update (Bentur and Koren). 1991;165:429-37 (Curr. dev.)

Computers

Computerized analysis of episodic changes in fetal heart rate variation in early labor (Dawes et al). 1991;165:618-24

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14 Short-term variation in abnormal antenatal fetal heart rate records (Street et al). 1991;165:515-23

Condylomata acuminata

Treatment failure of genital condylomata acuminata in women: role of the male sexual partner (Krebs and Helmkamp). 1991;165:337-40

Vulvovaginal human papillomavirus infections: clinical implications and management (Hatch). 1991;165: 1183-8

Congenital defects; see Abnormalities

Congenital hydronephrosis; see Hydronephrosis Consultants

Consultants for the American Journal of Obstetrics and Gynecology, September 1, 1990—August 31, 1991. 1991; 165:1579-94

Contraception

Alternative estimates of ectopic pregnancy risks during contraception (Sivin) (Letter); (Franks and Beral) (Reply). 1991;165:1899-900

Daily administration of the progesterone antagonist RU 486 prevents implantation in the cycling guinea pig (Batista et al). 1991;165:82-6

The fertility awareness method: extent of use, potential, and research needs (Williamson). 1991;165:2076 (Abstract)

Contraceptives, oral

Nonbarrier contraceptives and vaginitis and vaginosis (Roy). 1991:165:1240-4

Single and multiple administration of a new triphasic oral contraceptive to women: pharmacokinetics of ethinyl estradiol and free and total testosterone levels in serum (Kuhnz et al). 1991;165:596-602

Contraction, uterine; see Uterine contraction

Cord blood; see Fetal blood

Cordocentesis; see Fetal blood, analysis

Cornual pregnancy; see Pregnancy, ectopic Corrections

Does unexplained second trimester (15 to 20 weeks' gestation) maternal serum α -fetoprotein elevation presage adverse perinatal outcome? (Simpson et al) (1991;164:829-36). 1991;165:241

A mechanism leading to reduced lung expansion and lung hypoplasia in fetal sheep during oligohydramnios (Harding et al) (1990;163:1904-13). 1991;165:491

Placental pathologic findings in preterm birth (Salafia et al) (1991;165:934-8) 1991;165:1903

Position change and central hemodynamic profile during normal third-trimester pregnancy and post partum (Clark et al) (1991;164:883-7). 1991;165:241

The therapeutic efficacy and cost-effectiveness of aggressive tocolysis for premature labor associated with premature rupture of the membranes (Weiner et al) (1988;159:216-22). 1991;165:785

Correspondence

Letters. 1991;165:235-41, 482-9, 779-85, 1156-61, 1575-7,

Corticosteroids; see Adrenal cortex hormones Corticotropin; see Adrenocorticotropic hormone Cost benefit analysis

Evaluation of natural family planning programs in Liberia and Zambia (Kambic et al). 1991;165:2078 (Abstract)

Natural family planning program format effectiveness (Kramer). 1991;165:2078 (Abstract)

Operations research in natural family planning: strategies, issues, and research approaches (Ricci et al). 1991;165:2077-8 (Abstract)

Cote d'Ivoire

Expanding natural family planning through vocational schools for women in Cote d'Ivoire (Rodriguez-Garcia). 1991;165:2073 (Abstract)

Couple-years protection

Measuring natural family planning in terms of couple-years of protection (Cuervo). 1991;165:2063-5

Creatinine

Urinary protein/creatinine ratio before and during pregnancy in women with diabetes mellitus (Combs et al). 1991;165:920-3

Cryopreservation

Partial dissection of the zona pellucida of frozen-thawed human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Cryosurgery

Ten years after cryosurgical treatment of cervical intraepithelial neoplasia (Dræby-Kristiansen et al). 1991;165:43-5

Current development

Current development. 1991;165:160-72, 429-37, 745-9

Cushing's syndrome

A case report of prostaglandin E₂ termination of pregnancy complicated by Cushing's syndrome (Buescher et al). 1991;165:1412-3

Cutaneous vasculitis; see Vasculitis, allergic cutaneous Cysts

Are choroid plexus cysts an indication for second-trimester amniocentesis? (Achiron and Mashiach) (Letter); (Benacerraf) (Reply). 1991;165:239-41

Porencephalic cyst: a complication of fetal intravascular transfusion (Dildy et al). 1991;165:76-8

Cytokines

Endothelin production by amnion and its regulation by cytokines (Mitchell et al). 1991;165:120-4

Expression of cytokine receptors and markers of differentiation in human papillomavirus—infected cervical tissues (McGlennen et al). 1991;165:696-705

Neutrophil attractant/activating peptide-1/interleukin-8 in term and preterm parturition (Romero et al). 1991; 165:813-20

Systemic administration of interleukin-1 induces preterm parturition in mice (Romero et al). 1991;165: 969-71

Cytology

The association between human papillomavirus deoxyribonucleic acid status and the results of cytologic rescreening tests in young, sexually active women (Moscicki et al). 1991;165:67-71

Cytomegaloviruses

Prenatal diagnosis of fetal cytomegalovirus infection (Lynch et al). 1991;165:714-8

Cytotoxicity, immunologic

Increased progesterone concentrations are necessary to suppress interleukin-2-activated human mononuclear cell cytotoxicity (Feinberg et al). 1991;165:1872-6

Cytotrophoblast; see Trophoblasts

D

Decidua

Isolation and purification of microvascular endothelium from human decidual tissue in the late phase of pregnancy (Gallery et al). 1991;165:191-6

Decidual tissue; see Decidua

Decompression sickness

The effect of the menstrual cycle and of decompression stress on arachidonic acid—induced platelet aggregation and on intrinsic platelet thromboxane production in women compared with men (Markham et al). 1991;165:1821-9

Deep venous thrombosis; see Thrombophlebitis

Dehiscence; see Surgical wound dehiscence

Dehydroepiandrosterone

Adrenal and ovarian steroid hormone responses to gonadotropin-releasing hormone agonist treatment in polycystic ovary syndrome (Gonzalez et al). 1991;165: 535-45

Is 11β-hydroxyandrostenedione a better marker of adrenal androgen excess than dehydroepiandrosterone sulfate? (Stanczyk et al). 1991;165:1839-42

Delivery

External cephalic version after previous cesarean section (Flamm et al). 1991;165:370-2

The fetal-pelvic index: a method of identifying fetal-pelvic disproportion in women attempting vaginal birth after previous cesarean delivery (Thurnau et al). 1991;165: 353-8

Funic reduction for the management of umbilical cord prolapse (Barrett). 1991;165:654-7

Twin delivery: influence of the presentation and method of delivery on the second twin (Adam et al). 1991;165:23-7

Delivery, injuries

Shoulder dystocia and birth trauma in gestational diabetes: a five-year experience (Keller et al). 1991;165:928-30

Delivery of health care

Current natural family planning programs and strategies for expanding service delivery: an introduction (Mejia and Solis). 1991;165:2072 (Abstract)

New approaches to expanding natural family planning (Skipp). 1991;165:2072 (Abstract)

Service delivery part 1: current programs and strategies for expansion (Mejia et al). 1991;165:2072-3 (Abstract)

Service delivery part 2: elements necessary for success (Jennings et al). 1991;165:2073-4 (Abstract)

At what stage is natural family planning service delivery? (Klaus). 1991;165:2076 (Abstract)

Denervation

Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al). 1991;165:745-9 (Curr. dev.)

Deoxyribonucleic acid; see DNA

Deoxyribonucleic acid probes; see DNA probes

Depression

Recurrent mild abruptio placentae occurring immediately after repeated electroconvulsive therapy in pregnancy (Sherer et al). 1991;165:652-3

Dermatitis

Pemphigus gestationis (herpes gestationis): a case report (Wolman et al). 1991;165:743-4

Vulvitis and vulvovaginitis: cutaneous considerations (McKay). 1991;165:1176-82

Detrusor muscle

The role of prostaglandins in detrusor instability (Bergman et al). 1991;165:1833-6

Diabetes mellitus

Incidence and risk factors associated with abnormal postpartum glucose tolerance in women with gestational diabetes (Catalano et al). 1991;165:914-9

The role of repeat glucose tolerance tests in the diagnosis

Diabetes mellitus-cont'd

of gestational diabetes (Neiger and Coustan). 1991; 165:787-90

Screening recommendations for gestational diabetes mellitus (Cousins et al). 1991;165:493-6 (Clin. opinion)

Shoulder dystocia: Should the fetus weighing ≥4000 grams be delivered by cesarean section? (Langer et al). 1991;165:831-7

Shoulder dystocia and birth trauma in gestational diabetes: a five-year experience (Keller et al). 1991;165:928-30

Urinary protein/creatinine ratio before and during pregnancy in women with diabetes mellitus (Combs et al). 1991;165:920-3

Diabetes mellitus, animal

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis (Finley and Norton). 1991;165:1661-6

The metabolic clearance rate of epinephrine in the fetus of the diabetic ewe (Dickinson et al). 1991;165:1655-60

Diabetes mellitus, experimental

Streptozocin-induced diabetes mellitus in the pregnant ewe (Dickinson et al). 1991;165:1673-7

Diabetic pregnancies; see Pregnancy in diabetes Diagnostic tests

A ràpid visual test for predicting fetal lung maturity (Sbarra et al). 1991;165:1351-3

Diamine oxidase; see Histaminase

Diaphragmatic hernia; see Hernia, diaphragmatic Diethylstilbestrol

Vaginal cancer: the role of infectious and environmental factors (Merino). 1991;165:1255-62

Differentiation markers; see Antigens, differentiation Digoxin

Concentration of digoxin-like immunoreactive substance in patients with preeclampsia and its relation to severity of pregnancy-induced hypertension (Kaminski and Rechberger). 1991;165:733-6

Treatment of fetal supraventricular tachycardia with flecainide acetate after digoxin failure (Kofinas et al). 1991;165:630-1

Dinoprostone

Acute myocardial infarction associated with prostaglandin E₂ (Meyer et al). 1991;165:359-60

A case report of prostaglandin E₂ termination of pregnancy complicated by Cushing's syndrome (Buescher et al). 1991;165:1412-3

Maturation of the uterine cervix by repeated intracervical instillation of prostaglandin E₂ (Milliez et al). 1991;165:523-8

Patterns of uterine activity after intravaginal prostaglandin E₂ during preinduction cervical ripening (Miller et al). 1991;165:1006-9

A randomized, double-blind trial of prostaglandin $\rm E_2$ gel for cervical ripening and meta-analysis (Owen et al). 1991;165:991-6

Uterine and fetal Doppler flow changes after intravaginal prostaglandin E₂ therapy for cervical ripening (Rayburn et al). 1991;165:125-6

Uterine rupture at term pregnancy with the use of intracervical prostaglandin E₂ gel for induction of labor (Maymon et al). 1991;165:368-70

Disclosure; see Truth disclosure

Disease models, animal

A rabbit model for bacterially induced preterm pregnancy loss: intervention studies with ampicillin-sulbactam (McDuffie et al). 1991;165:1568-74

DNA

Sister chromatid exchange frequency in directly prepared cytotrophoblasts: demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes (Shulman et al). 1991;165:1877-80

DNA probes

Detection of *Chlamydia trachomatis* endocervical infection in asymptomatic and symptomatic women: comparison of deoxyribonucleic acid probe test with tissue culture (Yang et al). 1991;165:1444-53

DNA probes, HPV

The association between human papillomavirus deoxyribonucleic acid status and the results of cytologic rescreening tests in young, sexually active women (Moscicki et al). 1991;165:67-71

Documentation

Analysis of 500 obstetric and gynecologic malpractice claims: causes and prevention (Ward). 1991;165:298-306

Doppler ultrasonography; see Ultrasonography

Doppler velocimetry; see Flowmeters

Double guard-ring tocodynamometer; see Cardiotocography Down's syndrome

Comparison of humerus length with femur length in fetuses with Down syndrome (Rodis et al). 1991;165:1051-6

The effect of gestational age on the detection rate of Down's syndrome by maternal serum α-fetoprotein screening (Greenberg et al). 1991;165:1391-3

Free β-protein studies need confirmation (Goodlin) (Letter); (Macri et al) (Reply). 1991;165:779-80

Prenatal prediction of Down syndrome (Reynolds and Penney) (Letter); (O'Brien) (Reply). 1991;165:781-2

Prospective evaluation of maternal serum human chorionic gonadotropin levels in 3428 pregnancies (Bogart et al). 1991:165:663-7

Ultrasonographic screening for the Down syndrome fetus (Lockwood et al). 1991;165:349-52 (Clin. opinion)

Doxorubicin

Combined interferon alfa and doxorubicin in the treatment of advanced cervical cancer (Welander et al). 1991;165:284-91

Drug screening assays, antitumor

Characterization of in vitro chemosensitivity of perioperative human ovarian malignancies by adenosine triphosphate chemosensitivity assay (Gerhardt et al). 1991;165:245-55

Drug therapy

CA 125 regression: a model for epithelial ovarian cancer response (Buller et al). 1991;165:360-7

Combined interferon alfa and doxorubicin in the treatment of advanced cervical cancer (Welander et al). 1991;165:284-91

Hexamethylmelamine chemotherapy for persistent or recurrent epithelial ovarian cancer (Moore et al). 1991;165:573-6

Drugs

Medication in early pregnancy: prevalence of use and relationship to maternal characteristics (Buitendijk and Bracken). 1991;165:33-40

Ductus arteriosus, animal

Acute fetal ductal occlusion in lambs (Tulzer et al). 1991;165:775-8

Dysautonomia, familial

Cesarean section by local anesthesia in patients with familial dysautonomia (Leiberman et al). 1991;165:110-1

Dysmenorrhea

Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al). 1991;165:745-9 (Curr. dev.)

Relationship between the onset of dysmenorrhea and histologic findings in adenomyosis (Nishida). 1991;165:229-31 (Symposium)

Dyspareunia

Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al). 1991;165:745-9 (Curr. dev.)

Vulvar vestibulitis syndrome: an overview (Marinoff and Turner). 1991;165:1228-33

Dystocia

Shoulder dystocia: Should the fetus weighing ≥4000 grams be delivered by cesarean section? (Langer et al). 1991;165:831-7

Shoulder dystocia and birth trauma in gestational diabetes: a five-year experience (Keller et al). 1991;165:928-30

F

Early pregnancy; see Pregnancy trimester, first Eating disorders

Infertility and eating disorders (McCluskey et al) (Letter); (Stewart) (Reply). 1991;165:1576-7

Echocardiography

Acute fetal ductal occlusion in lambs (Tulzer et al). 1991:165:775-8

Fetal cardiac function in intrauterine growth retardation (Rizzo and Arduini). 1991;165:876-82

Hypoplastic left heart syndrome: prenatal diagnosis, clinical profile, and management (Blake et al). 1991;165:529-34

Transvaginal fetal echocardiography in early pregnancy: normative data (Dolkart and Reimers). 1991;165:688-91

When do cardiovascular parameters return to their preconception values? (Capeless and Clapp). 1991;165:883-6

Eclampsia

Epidemiology of preeclampsia and eclampsia (Ales and Charlson) (Letter); (Saftlas et al) (Reply). 1991;165:238

Economics

Natural family planning program format effectiveness (Kramer). 1991;165:2078 (Abstract)

Various forms of financial support for natural family planning teachers (Lanctôt). 1991;165:2076 (Abstract)

Ectopic pregnancy; see Pregnancy, ectopic Ectopic tissue; see Choristoma

Edema

A case report of massive vulvar edema during tocolysis of preterm labor (Brittain et al). 1991;165:420-2

Editorial

Editorial. 1991;165:1

Education

Competency-based approach to training and natural family planning instructor standards (Martin). 1991;165:2069 (Abstract)

The development of the International Federation for Family Life Promotion training guide (Martin). 1991;165:2072 (Abstract)

An experiential approach to training natural family planning trainers (Aumack). 1991;165:2069 (Abstract)

The "Guide for Natural Family Planning Trainers" (Aumack). 1991;165:2072 (Abstract)

Introduction and overview of natural family planning training programs (Vogelsang). 1991;165:2069 (Abstract)

Introduction of natural family planning information into multimethod materials for trainers (Lea and Murphy). 1991;165:2071 (Abstract)

Natural family planning training issues and strategies for the 1990s (Aumack et al). 1991;165:2069 (Abstract)

Preparing instructors to educate diverse client populations: the impact of culture, religion, socioeconomic status, and educational levels (Mascarenhas). 1991;165:2069 (Abstract)

Training and supervision from small natural family planning programs to national service delivery systems (Mwaulu), 1991;165:2069 (Abstract)

Training evaluation: its impact on future instructor training, client education, and natural family planning services (Walter). 1991;165:2069 (Abstract)

Education of patient; see Patient education

Egg transport; see Ovum transport

Electric conductivity

The effects of electric field-mediated transfer of nonpermeable molecules of meiosis, fertilization, and early embryo development (Douglas et al). 1991;165: 1480-6

Electrocardiography, ambulatory

Home monitoring of uterine contractility (Rhoads et al). 1991;165:2-6 (Clin. opinion)

Electroconvulsive therapy

Recurrent mild abruptio placentae occurring immediately after repeated electroconvulsive therapy in pregnancy (Sherer et al). 1991;165:652-3

Electrosurgery, animal

The interaction of electrosurgical bipolar forceps and generators on an animal model of fallopian tube sterilization (Tucker et al). 1991;165:443-9

Embryo

Factors affecting embryo implantation after human in vitro fèrtilization (Meldrum) (Letter); (Paulson and Sauer) (Reply). 1991;165:1896-7

Multifetal pregnancy reduction and disposal of untransplanted embryos in contemporary Jewish law and ethics (Grazi and Wolowelsky). 1991;165:1268-71 (Clin. opinion)

Partial dissection of the zona pellucida of frozen-thawed human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Embryo, animal

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis (Finley and Norton), 1991;165;1661-6

Embryo development; see Fetal development

Endocrine diseases

Prolonged exposure to wood preservatives induces endocrine and immunologic disorders in women (Gerhard et al). 1991;165:487-8 (Letter)

Endocrine system

Endocrine effects in female weight lifters who self-administer testosterone and anabolic steroids (Malarkey et al). 1991;165:1385-90

Endoloop sutures; see Sutures

Endometrial neoplasms; see Uterine neoplasms

1942 Subject index December 1991 Am J Obstet Gynecol

Endometriosis

Effects of peritoneal macrophages from patients with endometriosis on the proliferation of endometrial carcinoma cell line ECC-1 (Zhang et al). 1991;165:1842-6

Histologic study of endometriosis and examination of lymphatic drainage in and from the uterus (Ueki). 1991;165:201-9 (Symposium)

Pathogenesis of endometriosis and adenomyosis: introductory remarks (Taketani et al). 1991;165:197 (Symposium)

Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al). 1991;165:745-9 (Curr. dev.)

Peritoneal endometriosis: endometrial tissue implantation as its primary etiologic mechanism (Ishimaru and Masuzaki). 1991;165:210-4 (Symposium)

A reappraisal of the coelomic metaplasia theory by reviewing endometriosis occurring in unusual sites and instances (Suginami). 1991;165:214-8 (Symposium)

Relationship between the onset of dysmenorrhea and histologic findings in adenomyosis (Nishida). 1991;165:229-31 (Symposium)

Secondary müllerian system and endometriosis (Fujii). 1991;165:219-25 (Symposium)

Subserosal adenomyosis: a possible variant of pelvic endometriosis (Sakamoto). 1991;165:198-201 (Symposium)

Ultrastructural study of glandular epithelium in adenomyosis in comparison with those of proliferative endometrium and well-differentiated endometrial cancer (Hayata). 1991;165:225-8 (Symposium)

Endometriosis, animal

Animal model of uterine adenomyosis: Is prolactin a potent inducer of adenomyosis in mice? (Mori et al). 1991;165:232-4 (Symposium)

Peritoneal endometriosis: endometrial tissue implantation as its primary etiologic mechanism (Ishimaru and Masuzaki). 1991;165:210-4 (Symposium)

Endometrium

Effect of clomiphene citrate treatment on endometrial estrogen and progesterone receptor induction in women (Fritz et al). 1991;165:177-85

Measurement of human epidermal growth factor receptor in the endometrium during the menstrual cycle (Troche et al). 1991;165:1499-503

A prospective, randomized comparison of the Pipelle endometrial sampling device with the Novak curette (Stovall et al). 1991;165:1287-9

Ultrasonographic visualization of endometrial vascularity with ectopic pregnancy (Cadkin and Applebaum). 1991:165:236 (Letter)

Endomyocardial ultrastructural findings; see Myocardium, ultrastructure

Endoscopy

Transcervical endoscopic verification of congenital anomalies in the second trimester of pregnancy (Cullen et al). 1991;165:95-7

Endothelins

Endothelin-1-induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation (Myatt et al). 1991;165:1717-22

Endothelin production by amnion and its regulation by cytokines (Mitchell et al). 1991;165:120-4

Maternal plasma level of endothelin is increased in preeclampsia (Nova et al). 1991;165:724-7

Potential role of endothelin-1 in normal and hypertensive pregnancies (Mastrogiannis et al). 1991;165:1711-6

Endothelium

Isolation and purification of microvascular endothelium from human decidual tissue in the late phase of pregnancy (Gallery et al). 1991;165:191-6

Endothelium, vascular

Anticardiolipin antibody-positive serum enhances endothelial cell platelet-activating factor production (Silver et al). 1991;165:1748-52

An endothelial cell model for the investigation of the molecular regulation of fetal vascular tone (Dudley et al). 1991;165:1723-6

Relaxation of the human uterine artery by atrial natriuretic peptide is independent of the endothelium (Bodelsson et al). 1991;165:483-4 (Letter)

Selective effects of preeclamptic sera on human endothelial cell procoagulant protein expression (Taylor et al). 1991;165:1705-10

Endothelium-derived relaxing factor

Enhanced endothelium-derived relaxing factor activity in pregnant, spontaneously hypertensive rats (Ahokas et al). 1991;165:801-7

Environmental exposure

The three most common occupational exposures reported by pregnant women: an update (Bentur and Koren). 1991;165:429-37 (Curr. dev.)

Vaginal cancer: the role of infectious and environmental factors (Merino). 1991;165:1255-62

Enzyme-linked immunosorbent assay

Rapid enzyme-linked immunoassay tests for group B streptococcus infection (Green et al). 1991;165:486-7 (Letter)

Eosinophils

Association of immunoreactive eosinophil major basic protein with placental septa and cysts (Wasmoen et al). 1991;165:416-20

Epidermal growth factor receptor; see Receptors, epidermal growth factor-urogastrone

Epidermal growth factor-urogastrone

Cytologic localization of epidermal growth factor and its receptor in developing human placenta varies over the course of pregnancy (Ladines-Llave et al). 1991;165: 1377-82

Effects of maternally administered epidermal growth factor on placental permeability (Mimouni et al). 1991;165:173-6

Epinephrine

The metabolic clearance rate of epinephrine in the fetus of the diabetic ewe (Dickinson et al). 1991;165:1655-60

Epithelial ovarian cancer; see Ovarian neoplasms Epithelium

Ultrastructural study of glandular epithelium in adenomyosis in comparison with those of proliferative endometrium and well-differentiated endometrial cancer (Hayata). 1991;165:225-8 (Symposium)

Epitrochlearis muscle, animal; see Muscles, animal Epoprostenol

An endothelial cell model for the investigation of the molecular regulation of fetal vascular tone (Dudley et al). 1991;165:1723-6

The imbalance between thromboxane and prostacyclin in preeclampsia is associated with an imbalance between lipid peroxides and vitamin E in maternal blood (Wang et al). 1991;165:1695-700

Maternal levels of prostacyclin, thromboxane, vitamin E, and lipid peroxides throughout normal pregnancy (Wang et al). 1991;165:1690-4

- Reduction of primary posttraumatic adhesion formation with the prostacyclin analog iloprost in a rodent model (Steinleitner et al). 1991;165:1817-20
- The role of prostaglandins in detrusor instability (Bergman et al). 1991;165:1833-6
- Simultaneous measurements of prostacyclin and thromboxane metabolites during the menstrual cycle (Presser et al). 1991;165:647-51

Equipment and supplies

- Automated analysis of near-term antepartum fetal heart rate in relation to fetal behavioral states: the Sonicaid System 8000 (Mantel et al). 1991;165:57-65
- The interaction of electrosurgical bipolar forceps and generators on an animal model of fallopian tube sterilization (Tucker et al). 1991;165:443-9
- A prospective, randomized comparison of the Pipelle endometrial sampling device with the Novak curette (Stovall et al). 1991;165:1287-9
- Qualitative evaluation of uterine contractions recorded by a double guard-ring tocodynamometer (Shinmoto et al). 1991;165:1282-6

Ergosterol

Mode of action of anti-Candida drugs: focus on terconazole and other ergosterol biosynthesis inhibitors (Vanden Bossche and Marichal). 1991;165:1193-9

Erythroblastosis, fetal

- Amniotic fluid bilirubin and fetal hemolytic disease (Spinnato et al). 1991;165:1030-5
- Hyporegenerative anemia associated with intrauterine transfusion in rhesus hemolytic disease (Thorp et al). 1991:165:79-81
- Management of fetal hemolytic disease by cordocentesis. I. Prediction of fetal anemia (Weiner et al). 1991;165:546-53
- Management of fetal hemolytic disease by cordocentesis. II.

 Outcome of treatment (Weiner et al). 1991;165:
 1302-7

Erythromycin

- Antimicrobial therapy in preterm premature rupture of membranes: results of a prospective, double-blind, placebo-controlled trial of erythromycin (McGregor et al). 1991;165:632-40
- Comparative efficacy of clindamycin versus erythromycin in eradication of antenatal *Chlamydia trachomatis* (Alger and Lovchik). 1991;165:375-81

Esophagostomy

Uterine and fetal Doppler flow changes after intravaginal prostaglandin E₂ therapy for cervical ripening (Rayburn et al). 1991;165:125-6

Esophagus, animal

Amniotic fluid volume response to esophageal occlusion in fetal sheep (Fujino et al). 1991;165:1620-6

Estradio

- Forward shift in the initiation of the nocturnal estradiol surge in the pregnant baboon: Is this the genesis of labor? (Wilson et al). 1991;165:1487-98
- Prolonged clearance of intraperitoneal 16α-[¹²⁵I]iodo-17β-estradiol in presence of ascites (Scharl et al). 1991; 165:1847-53

Estrogen receptor; see Receptors, estrogen

Estrogen replacement therapy

- Changes in lipids and lipoproteins with long-term estrogen deficiency and hormone replacement therapy (Gambrell and Teran). 1991;165:307-17
- Gonadotropin-releasing hormone agonist and estrogen-

progestogen replacement therapy (Gudmundsson et al) (Letter); (Barbieri) (Reply). 1991;165:1156-7

Estrogens

Changes in lipids and lipoproteins with long-term estrogen deficiency and hormone replacement therapy (Gambrell and Teran). 1991;165:307-17

Ethics

- Ethics in medical studies with human subjects (Sherer and Abramowicz) (Letter); (Goldstein and Zimmer) (Reply). 1991;165:1895-6
- Is opposition to abortion unethical? (Calvin) (Letter); (Chervenak and McCullough) (Reply). 1991;165:782-3
- Multifetal pregnancy reduction and disposal of untransplanted embryos in contemporary Jewish law and ethics (Grazi and Wolowelsky). 1991;165:1268-71 (Clin. opinion)

Ethinyl estradiol

Single and multiple administration of a new triphasic oral contraceptive to women: pharmacokinetics of ethinyl estradiol and free and total testosterone levels in serum (Kuhnz et al). 1991;165:596-602

Exercise

- Assessment of Kegel pelvic muscle exercise performance after brief verbal instruction (Bump et al). 1991;165:322-9
- The changing glycemic response to exercise during pregnancy (Clapp and Capeless). 1991;165:1678-83
- The changing thermal response to endurance exercise during pregnancy (Clapp). 1991;165:1684-9

External cephalic version; see Version, fetal

Extracellular matrix

Expression of extracellular matrix—degrading metalloproteinases by cultured human cytotrophoblast cells: effects of cell adhesion and immunopurification (Bischof et al). 1991;165:1791-801

F

Fallopian tube neoplasms

A plea for early diagnosis of fallopian tube carcinoma: Can hysteroscopy be of use? (Sholapurkar). 1991;165:483 (Letter)

Fallopian tube sterilization, animal; see Sterilization, tubal, animal

Fallopian tubes

Improvement of in vitro fertilization and early embryo development in mice by coculture with human fallopian tube epithelium (Goldberg et al). 1991;165:1802-5

Familial dysautonomia; see Dysautonomia, familial

Comparison of humerus length with femur length in fetuses with Down syndrome (Rodis et al). 1991;165: . 1051-6

Fertility

Home tests to monitor fertility (May). 1991;165:2000-2 Symptothermal and hormonal markers of potential fertility in climacteric women (Flynn et al). 1991;165:1987-9

Fertility awareness method

The fertility awareness method: extent of use, potential, and research needs (Williamson). 1991;165:2076 (Abstract)

Fertilization

- The effects of electric field—mediated transfer of nonpermeable molecules of meiosis, fertilization, and early embryo development (Douglas et al). 1991;165:1480-6
- Human cervical mucus: research update (Katz). 1991; 165:1984-6

Fertilization in vitro

- Comparison of intermittent and continuous use of a gonadotropin-releasing hormone antagonist (Nal-Glu) in in vitro fertilization cycles: a preliminary report (Cassidenti et al). 1991;165:1806-10
- Factors affecting embryo implantation after human in vitro fertilization (Meldrum) (Letter); (Paulson and Sauer) (Reply). 1991;165:1896-7
- The influence of contamination of culture medium with hepatitis B virus on the outcome of in vitro fertilization pregnancies (van Os et al). 1991;165:152-9
- Partial dissection of the zona pellucida of frozen-thawed human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Fertilization in vitro, animal

Improvement of in vitro fertilization and early embryo development in mice by coculture with human fallopian tube epithelium (Goldberg et al). 1991;165:1802-5

Fetal behavior; see Fetal movement

Fetal blood

- Atrial natriuretic peptide: A vasodilator of the fetoplacental circulation? (Kingdom et al). 1991;165:791-800
- Bleeding after intravascular transfusion: experimental and clinical observations (Segal et al). 1991;165:1414-8
- Fetal blood sampling in patients undergoing elective cesarean section: a correlation with cord blood gas values obtained at delivery (Khoury et al). 1991;165: 1026-9
- Prenatal diagnosis of fetal cytomegalovirus infection (Lynch et al). 1991;165:714-8
- Risk factors for cordocentesis and fetal intravascular transfusion (Weiner et al). 1991;165:1020-5

Fetal blood, analysis

- Enhanced sensitization after cordocentesis in a rhesusisoimmunized pregnancy (MacGregor et al). 1991;165: 382-3
- Management of fetal hemolytic disease by cordocentesis. I. Prediction of fetal anemia (Weiner et al). 1991;165:546-53
- Management of fetal hemolytic disease by cordocentesis. II.

 Outcome of treatment (Weiner et al). 1991;165:1302-7
- Risk factors for cordocentesis and fetal intravascular transfusion (Weiner et al). 1991;165:1020-5

Fetal blood, animal

- Amnioinfusion increases amniotic pressure in pregnant sheep but does not alter fetal acid-base status (Fisk et al). 1991;165:1459-63
- Elevated fetal plasma lactate produces polyhydramnios in the sheep (Powell and Brace). 1991;165:1595-607
- Hemorrhage-induced reductions in plasma atrial natriuretic factor in the ovine fetus (Cheung and Brace). 1991;165:474-81

Fetal death

- Lack of an association between late fetal death and antiphospholipid antibody measurements in the second trimester (Haddow et al). 1991;165:1308-12
- Maternal perception of decreased fetal movement as an indication for antepartum testing in a low-risk population (Whitty et al). 1991;165:1084-8
- The origin of brain lesions in survivors of twin gestations complicated by fetal death (Gonen). 1991;165:1897-8 (Letter)
- On reducing the frequency of severe abruptio placentae (Pritchard et al). 1991;165:1345-51

Short-term variation in abnormal antenatal fetal heart rate records (Street et al). 1991;165:515-23

Fetal death, animal

A rabbit model for bacterially induced preterm pregnancy loss: intervention studies with ampicillin-sulbactam (McDuffie et al). 1991;165:1568-74

Fetal development

- The cheek-to-cheek diameter in the ultrasonographic assessment of fetal growth (Abramowicz et al). 1991;165:846-52
- Does amniotic fluid index affect the accuracy of estimated fetal weight in preterm premature rupture of membranes? (Toohey et al). 1991;165:1060-2
- The effect of maternal hemodynamics on fetal growth in hypertensive pregnancies (Easterling et al). 1991;165: 902-6
- The effects of electric field—mediated transfer of nonpermeable molecules of meiosis, fertilization, and early embryo development (Douglas et al). 1991;165: 1480-6
- Embryonic ultrasonographic measurements: crown-rump length revisited (Goldstein). 1991;165:497-501 (Clin. opinion)
- Predictive value of early embryonic cardiac activity for pregnancy outcome (Merchiers et al). 1991;165:11-4
- The three most common occupational exposures reported by pregnant women: an update (Bentur and Koren). 1991;165:429-37 (Curr. dev.)

Fetal development, animal

Improvement of in vitro fertilization and early embryo development in mice by coculture with human fallopian tube epithelium (Goldberg et al). 1991;165:1802-5

Fetal diseases

- The association between fetal karyotype and mean corpuscular volume (Sipes et al). 1991;165:1371-6
- Porencephalic cyst: a complication of fetal intravascular transfusion (Dildy et al). 1991;165:76-8
- Ultrasonographic screening for the Down syndrome fetus (Lockwood et al). 1991;165:349-52 (Clin. opinion)

Fetal diseases, animal

Fetal hypertension induced by norepinephrine infusion and umbilical artery flow velocity waveforms in fetal sheep (van Huisseling et al). 1991;165:450-5

Fetal distress

- Oligohydramnios: antepartum fetal urine production and intrapartum fetal distress (Groome et al). 1991;165:1077-80
- Variable decelerations in reactive nonstress tests with decreased amniotic fluid index predict fetal compromise (Hoskins et al). 1991;165:1094-8

Fetal growth retardation

- Arterial blood flow velocity waveforms of the pelvis and lower extremities in normal and growth-retarded fetuses (Mari). 1991;165:143-51
- The effect of maternal hemodynamics on fetal growth in hypertensive pregnancies (Easterling et al). 1991;165: 902-6
- Fetal cardiac function in intrauterine growth retardation (Rizzo and Arduini). 1991;165:876-82
- Fibrinolytic parameters in normotensive pregnancy with intrauterine fetal growth retardation and in severe preeclampsia (Estellés et al). 1991;165:138-42
- Postnatal outcome depends on prenatal history (Giorlandino) (Letter); (Lipper) (Reply). 1991;165:1159-60
- The prevalence of autoantibodies during third-trimester

- pregnancy complicated by hypertension or idiopathic fetal growth retardation (Milliez et al). 1991;165:51-6
- The relationship between umbilical artery Doppler velocimetry and fetal biometry (Scorza et al). 1991;165:1013-9
- Transverse cerebellar diameter: a useful predictor of gestational age for fetuses with asymmetric growth retardation (Lee et al). 1991;165:1044-50
- Twin gestation: influence of placentation on fetal growth (Pridjian et al). 1991;165:1394-401

Fetal heart

- Fetal cardiac function in intrauterine growth retardation (Rizzo and Arduini). 1991;165:876-82
- Pulmonary-to-aorta diameter ratio in the normal and abnormal fetal heart (Comstock et al). 1991;165:1038-44
- Transvaginal fetal echocardiography in early pregnancy: normative data (Dolkart and Reimers). 1991;165:688-91
- Treatment of fetal supraventricular tachycardia with flecainide acetate after digoxin failure (Kofinas et al). 1991;165:630-1

Fetal heart, animal

- Dose-dependent effects of angiotensin II on the ovine fetal cardiovascular system (Jones et al). 1991;165:1524-33
- Fetal cardiovascular and fluid responses to maternal volume loading with lactated Ringer's or hypotonic solutions (Powers and Brace). 1991;165:1504-15
- Role of endogenous atrial natriuretic factor in the regulation of fetal cardiovascular and renal function (Cheung). 1991;165:1558-67

Fetal heart rate; see Heart rate, fetal

Fetal hemolytic disease; see Erythroblastosis, fetal

Fetal intravascular transfusion; see Blood transfusion, intrauterine

Fetal macrosomia

Shoulder dystocia: Should the fetus weighing ≥4000 grams be delivered by cesarean section? (Langer et al). 1991;165:831-7

Fetal membranes

Aprotinin blocks the binding of pro atrial natriuretic peptides 1 to 30, 31 to 67, and 99 to 126 in human placental membranes (Vesely). 1991;165:567-73

Fetal membranes, premature rupture

- Antimicrobial therapy in preterm premature rupture of membranes: results of a prospective, double-blind, placebo-controlled trial of erythromycin (McGregor et al). 1991;165:632-40
- Correlation of amniotic fluid glucose concentration and intraamniotic infection in patients with preterm labor or premature rupture of membranes (Gauthier et al). 1991;165:1105-10
- Correlation of amniotic fluid index and nonstress test in patients with preterm premature rupture of membranes (Harding et al). 1991;165:1088-94
- Does amniotic fluid index affect the accuracy of estimated fetal weight in preterm premature rupture of membranes? (Toohey et al). 1991;165:1060-2
- Preterm premature rupture of membranes: detection of infection (Roussis et al). 1991;165:1099-104
- Rate of recurrence of preterm premature rupture of membranes in consecutive pregnancies (Asrat et al). 1991;165:1111-5
- Uterine activity after preterm premature rupture of the membranes (Campbell et al). 1991;165:422-5

Fetal monitoring

Antepartum fetal surveillance tests during sickle cell crisis (Anyaegbunam et al). 1991;165:1081-3

- Appropriateness of intrapartum fetal heart rate management and risk of cerebral palsy (Melone et al). 1991;165:272-7
- Correlation of amniotic fluid index and nonstress test in patients with preterm premature rupture of membranes (Harding et al). 1991;165:1038-94
- The dimension of chaos in the fetal heart rate (Chaffin et al). 1991;165:1425-9
- Home monitoring of uterine contractility (Rhoads et al). 1991;165:2-6 (Clin. opinion)
- Intrapartum course of fetuses with isolated hypoplastic left heart syndrome (Jackson et al). 1991;165:1068-72
- Maternal perception of decreased fetal movement as an indication for antepartum testing in a low-risk population (Whitty et al). 1991;165:1084-8
- Multicenter randomized clinical trial of home uterine activity monitoring for detection of preterm labor (Mou et al). 1991;165:858-66
- Preterm premature rupture of membranes: detection of infection (Roussis et al). 1991;165:1099-104
- Variable decelerations in reactive nonstress tests with decreased amniotic fluid index predict fetal compromise (Hoskins et al). 1991;165:1094-8

Fetal movement

- Automated analysis of near-term antepartum fetal heart rate in relation to fetal behavioral states: the Sonicaid System 8000 (Mantel et al). 1991;165:57-65
- The effect of fetal movement counting on maternal attachment to fetus (Mikhail et al). 1991;165:988-91
- Fetal breathing movements before oxytocin induction in prolonged pregnancies (Schreyer et al). 1991;165:577-81 Fetal movement during labor (Reddy et al). 1991;165:1073-
- Relationship between fetal biophysical activities and umbilical cord blood gas values (Vintzileos et al). 1991;165:707-13

Fetal movement, animal

Effects of vibration frequency and tissue thickness on intrauterine sound levels in sheep (Richards et al). 1991;165:438-42

Fetal organ maturity

- The effect of trisomy 18 on transverse cerebellar diameter (Hill et al). 1991;165:72-5
- The effects of betamethasone on maternal cellular resistance to infection (Cunningham and Evans). 1991:165:610-5
- The metabolic clearance rate of epinephrine in the fetus of the diabetic ewe (Dickinson et al). 1991;165:1655-60
- A rapid visual test for predicting fetal lung maturity (Sbarra et al). 1991;165:1351-3

Fetal-pelvic index

The fetal-pelvic index: a method of identifying fetal-pelvic disproportion in women attempting vaginal birth after previous cesarean delivery (Thurnau et al). 1991;165: 353-8

Fetal presentation; see Labor presentation

Fetus, animal

The effect of hypothalamic lesions on the length of gestation in fetal sheep (Gluckman et al). 1991;165:1464-8

Fetus, cytology

Prenatal diagnosis with fetal cells isolated from maternal blood by multiparameter flow cytometry (Price et al). 1991;165:1731-7

Fetus, drug effects

The effect of maternal cocaine use on the fetus: changes in

Fetus, drug effects-cont'd

antepartum fetal heart rate tracings (Tabor et al). 1991;165:1278-81

Fibrinolysis

Fibrinolytic parameters in normotensive pregnancy with intrauterine fetal growth retardation and in severe preeclampsia (Estellés et al). 1991;165:138-42

Fibronectins

High plasma cellular fibronectin levels correlate with biochemical and clinical features of preeclampsia but cannot be attributed to hypertension alone (Taylor et al). 1991;165:895-901

Filariasis

Human T-cell lymphotropic virus type I infection and pregnancy: a case-control study and 12-month follow-up of 135 women and their infants (Ville et al). 1991;165:1438-43

Financing

Various forms of financial support for natural family planning teachers (Lanctôt). 1991;165:2076 (Abstract)

Flecainide acetate

Treatment of fetal supraventricular tachycardia with flecainide acetate after digoxin failure (Kofinas et al). 1991;165:630-1

Flow cytometry

Expression of cytokine receptors and markers of differentiation in human papillomavirus—infected cervical tissues (McGlennen et al). 1991;165:696-705

Prenatal diagnosis with fetal cells isolated from maternal blood by multiparameter flow cytometry (Price et al). 1991;165:1731-7

Flowmeters

Doppler flow velocities in single umbilical arteries (Duerbeck et al). 1991;165:1120-2

The relationship between umbilical artery Doppler velocimetry and fetal biometry (Scorza et al). 1991;165:1013-9

Fluid therapy

Fetal cardiovascular and fluid responses to maternal volume loading with lactated Ringer's or hypotonic solutions (Powers and Brace). 1991;165:1504-15

Follicular phase

Cellular localization of müllerian inhibiting substance messenger ribonucleic acid during human ovarian follicular development (Whitman and Pantazis). 1991;165: 1881-6

The gonadotropin-releasing hormone antagonist (Nal-Glu) acutely blocks the luteinizing hormone surge but allows for resumption of folliculogenesis in normal women (Ditkoff et al). 1991;165:1811-7

Forceps; see Surgical instruments

Free radicals

Antioxidant systems in normal pregnancy and in pregnancy-induced hypertension (Wisdom et al). 1991;165: 1701-4

Fungi

Fungal morphology after treatment with itraconazole as a single oral dose in experimental vaginal candidosis in rats (Jansen et al). 1991;165:1552-7

Funic reduction

Funic reduction for the management of umbilical cord prolapse (Barrett). 1991;165:654-7

G

Gamma globulins

Congenital heart block: successful prophylactic treatment

with intravenous gamma globulin and corticosteroid therapy (Kaaja et al). 1991;165:1333-4

Generators; see Equipment and supplies

Genetic counseling

Single-center comparison of results of 1000 prenatal diagnoses with chorionic villus sampling and 1000 diagnoses with amniocentesis (Young et al). 1991;165:255-63

Transcervical endoscopic verification of congenital anomalies in the second trimester of pregnancy (Cullen et al). 1991:165:95-7

Genetic screening

Genetic identification of pregnancies responsible for choriocarcinomas after multiple pregnancies by restriction fragment length polymorphism analysis (Osada et al). 1991;165:682-8

Genetics

The prevalence of recurrent spontaneous abortions, cancer, and congenital anomalies in the families of couples with recurrent spontaneous abortions or gestational trophoblastic tumors (Ho et al). 1991;165:461-6

Genital diseases, female

Treatment failure of genital condylomata acuminata in women: role of the male sexual partner (Krebs and Helmkamp). 1991;165:337-40

Genital neoplasms, female

The Cherney incision for gynecologic cancer (Brand) (Letter); (Helmkamp) (Reply). 1991;165:235

Human papillomavirus infection in women with multicentric squamous cell neoplasia (Beckmann et al). 1991;165:1431-7

Genitalia, female

Renal agenesis in association with malformation of the female genital tract (Acién et al). 1991;165:1368-70

Genome; see Genomic library

Genomic library

Trophoblast from anembryonic pregnancy has both a maternal and a paternal contribution to its genome (Henderson et al). 1991;165:98-102

Germany

Effectiveness and acceptability of the symptothermal method of natural family planning in Germany (Frank-Herrmann et al). 1991;165:2052-4

Gestational age

The cheek-to-cheek diameter in the ultrasonographic assessment of fetal growth (Abramowicz et al). 1991; 165:846-52

The effect of gestational age on the detection rate of Down's syndrome by maternal serum α -fetoprotein screening (Greenberg et al). 1991;165:1391-3

Embryonic ultrasonographic measurements: crown-rump length revisited (Goldstein). 1991;165:497-501 (Clin. opinion)

Transverse cerebellar diameter: a useful predictor of gestational age for fetuses with asymmetric growth retardation (Lee et al). 1991;165:1044-50

Gestational diabetes; see Pregnancy in diabetes

Gestational trophoblastic tumor; see Trophoblastic tumor Glibenclamide

Insignificant transfer of glyburide occurs across the human placenta (Elliott et al). 1991;165:807-12

Glucose

The changing glycemic response to exercise during pregnancy (Clapp and Capeless). 1991;165:1678-83

Correlation of amniotic fluid glucose concentration and intraamniotic infection in patients with preterm labor or Volume 165
Number 6, Part 1
Subject index 1947

premature rupture of membranes (Gauthier et al). 1991;165:1105-10

Glucose tolerance test

Incidence and risk factors associated with abnormal postpartum glucose tolerance in women with gestational diabetes (Catalano et al). 1991;165:914-9

Longitudinal changes in insulin release and insulin resistance in nonobese pregnant women (Catalano et al). 1991:165:1667-72

The role of repeat glucose tolerance tests in the diagnosis of gestational diabetes (Neiger and Coustan). 1991; 165:787-90

Screening recommendations for gestational diabetes mellitus (Cousins et al). 1991;165:493-6 (Clin. opinion)

Glyburide; see Glibenclamide

Glycoproteins

New monoclonal antibodies identify the glycoprotein carrying the CA 125 epitope (O'Brien et al). 1991;165:1857-

Gonadal dysgenesis, 46,XY

The presence of the testicular determining sequence, SRY, in 46,XY females with gonadal dysgenesis (Swyer syndrome) (Behzadian et al). 1991;165:1887-90

Gonadorelin

Adrenal and ovarian steroid hormone responses to gonadotropin-releasing hormone agonist treatment in polycystic ovary syndrome (Gonzalez et al). 1991;165:535-45

Comparison of intermittent and continuous use of a gonadotropin-releasing hormone antagonist (Nal-Glu) in in vitro fertilization cycles: a preliminary report (Cassidenti et al). 1991;165:1806-10

Dose-related action of gonadotropin-releasing hormone on basal prostanoid production from the human term placenta (Kang et al). 1991;165:1771-6

Gonadotropin-releasing hormone agonist and estrogenprogestogen replacement therapy (Gudmundsson et al) (Letter); (Barbieri) (Reply). 1991;165:1156-7

The gonadotropin-releasing hormone antagonist (Nal-Glu) acutely blocks the luteinizing hormone surge but allows for resumption of folliculogenesis in normal women (Dit-koff et al). 1991;165:1811-7

Gonadotropin-releasing hormone; see Gonadorelin Gonadotropins, chorionic

Prospective evaluation of maternal serum human chorionic gonadotropin levels in 3428 pregnancies (Bogart et al). 1991:165:663-7

Granulosa cells

Lymphocytes stimulate progesterone production by cultured human granulosa luteal cells (Emi et al). 1991;165;1469-74

Group B streptococcus; see Streptococcus agalactiae Growth retardation; see Fetal growth retardation Growth substances

Inhibin subunits in human placenta: localization and messenger ribonucleic acid levels during pregnancy (Petraglia et al). 1991;165:750-8

Gynecologic cancer; see Genital neoplasms, female

Н

Haemophilus influenzae

A life-threatening sexually transmitted *Haemophilus influenzae* in septic abortion: a case report (Pinhas-Hamiel et al). 1991;165:66

Heart block

Congenital heart block: successful prophylactic treatment

with intravenous gamma globulin and corticosteroid therapy (Kaaja et al). 1991;165:1333-4

Heart defects, congenital

Congenital heart block: successful prophylactic treatment with intravenous gamma globulin and corticosteroid therapy (Kaaja et al). 1991;165:1333-4

Hypoplastic left heart syndrome: prenatal diagnosis, clinical profile, and management (Blake et al). 1991;165:529-24 Intrapartum course of fetuses with isolated hypoplastic left heart syndrome (Jackson et al). 1991;165:1068-72

Myocardial necrosis in a newborn after long-term maternal subcutaneous terbutaline infusion for suppression of preterm labor (Fletcher et al). 1991;165:1401-4

Pulmonary-to-aorta diameter ratio in the normal and abnormal fetal heart (Comstock et al). 1991;165: 1038-44

Steroid therapy for hydrops associated with antibody-mediated congenital heart block (Watson and Katz). 1991;165:553-4

Heart defects, congenital, animal

Acute fetal ductal occlusion in lambs (Tulzer et al). 1991;165:775-8

Heart rate, animal

Circadian rhythms of heart rate and mean arterial pressure in chronically instrumented pregnant rats (Melone et al). 1991;165:758-63

Heart rate, fetal

Appropriateness of intrapartum fetal heart rate management and risk of cerebral palsy (Melone et al). 1991; 165:272-7

Automated analysis of near-term antepartum fetal heart rate in relation to fetal behavioral states: the Sonicaid System 8000 (Mantel et al). 1991;165:57-65

Computerized analysis of episodic changes in fetal heart rate variation in early labor (Dawes et al). 1991;165:618-24

The dimension of chaos in the fetal heart rate (Chaffin et al). 1991;165:1425-9

The effect of maternal cocaine use on the fetus: changes in antepartum fetal heart rate tracings (Tabor et al). 1991;165:1278-81

Fetal atrioventricular and outflow tract flow velocity waveforms during normal second half of pregnancy (van der Mooren et al). 1991;165:668-74

Fetal heart rate response to vibroacoustic stimulation during low and high heart rate variability episodes in late pregnancy (Spencer et al). 1991;165:86-90

Fetal movement during labor (Reddy et al). 1991;165:1073-

Predictive value of early embryonic cardiac activity for pregnancy outcome (Merchiers et al). 1991;165:11-4

Short-term variation in abnormal antenatal fetal heart rate records (Street et al). 1991;165:515-23

Heart rate, fetal, animal

Dose-dependent effects of angiotensin II on the ovine fetal cardiovascular system (Jones et al). 1991;165:1524-33

Hematoma

Subchorionic hematomas and the presence of autoantibodies (Baxi and Pearlstone). 1991;165:1423-4

Hemodynamics

The effect of maternal hemodynamics on fetal growth in hypertensive pregnancies (Easterling et al). 1991;165: 902-6

Maternal hemodynamics in pregnancy (Baumann and Huch) (Letter); (Ikeda and Mori) (Reply). 1991;165:237-

Hemodynamics-cont'd

When do cardiovascular parameters return to their preconception values? (Capeless and Clapp). 1991;165:883-6

Hemodynamics, animal

Atrial natriuretic factor responses to volume expansion in pregnant and nonpregnant sheep (Bennett and Rose). 1991;165:1627-34

Fetal and maternal plasma atrial natriuretic factor responses to angiotensin II infusion (Ross et al). 1991;165:1635-41

Hemorrhage

Bleeding after intravascular transfusion: experimental and clinical observations (Segal et al). 1991;165:1414-8

Vasopressin pack for treatment of bleeding after myoma resection (Townsend). 1991;165:1405-7

Hemorrhage, animal

Hemorrhage-induced reductions in plasma atrial natriuretic factor in the ovine fetus (Cheung and Brace). 1991;165:474-81

Hemorrhagic endovasculitis

Report of fourteen cases of nonimmune hydrops fetalis in association with hemorrhagic endovasculitis of the placenta (Novak et al). 1991;165:945-50

Hemostatic techniques

Hemostatic wrapping of ruptured liver in two postpartum patients (Rittenberry et al). 1991;165:705-7

Heparin

Administration of heparin by subcutaneous infusion with a programmable pump (Floyd et al). 1991;165:931-3

Hepatitis B virus

The influence of contamination of culture medium with hepatitis B virus on the outcome of in vitro fertilization pregnancies (van Os et al). 1991;165:152-9

Hepatolenticular degeneration

Pregnancy and Wilson's disease (Chin) (Letter); (Dupont et al) (Reply). 1991;165:488-9

HER-2 proto-oncogene; see Proto-oncogenes Hernia, diaphragmatic

A five-year statewide experience with congenital diaphragmatic hernia (Wenstrom et al). 1991;165:838-42

Herpes genitalis

Maternal genital herpes and gender of offspring (Brown and Corey) (Letter); (McGregor) (Reply). 1991;165:784-5

Herpes gestationis

Pemphigus gestationis (herpes gestationis): a case report (Wolman et al). 1991;165:743-4

Herpes simplex virus

Natural killer cell cytotoxicity to herpes simplex virus-1—infected cells is not altered by pregnancy (Eriksen et al). 1991;165:965-8

Herpesvirus hominis

Vaginal cancer: the role of infectious and environmental factors (Merino). 1991;165:1255-62

Hexamethylmelamine

Hexamethylmelamine chemotherapy for persistent or recurrent epithelial ovarian cancer (Moore et al). 1991;165:573-6

Hiccup

Fetal hiccups and the umbilical ring (Collins). 1991; 165:1161 (Letter)

High blood pressure; see Hypertension

Hispanic Americans

Recombinant 8 syndrome: the pool of Hispanic pericentric inversion 8 carriers expands numerically and geographically (Izquierdo et al). 1991;165:1419-22

Histaminase

Failure to verify high activities of polyamine oxidase in pregnancy serum (Kumazawa et al). 1991;165:1457-8

HIV infection

Incidence and prevalence of human immunodeficiency virus infection in a prenatal population undergoing routine voluntary human immunodeficiency virus screening, July 1987 to June 1990 (Lindsay et al). 1991;165:961-4

HLA antigens

The prevalence of recurrent spontaneous abortions, cancer, and congenital anomalies in the families of couples with recurrent spontaneous abortions or gestational trophoblastic tumors (Ho et al). 1991;165:461-6

Home monitoring

Home tests to monitor fertility (May). 1991;165:2000-2 Use of the home ovarian monitor in pregnancy avoidance (Brown et al). 1991;165:2008-11

Hormone antagonists

Daily administration of the progesterone antagonist RU 486 prevents implantation in the cycling guinea pig (Batista et al). 1991;165:82-6

Hormone replacement therapy; see Estrogen replacement therapy

Hormones

Symptothermal and hormonal markers of potential fertility in climacteric women (Flynn et al). 1991;165:1987-9

HTI.V.

Human T-cell lymphotropic virus type I infection and pregnancy: a case-control study and 12-month follow-up of 135 women and their infants (Ville et al). 1991;165:1438-43

Human immunodeficiency virus infection; see HIV infection Human leukocyte antigen; see HLA antigens

Human papillomavirus DNA probes; see DNA probes, HPV Human papillomavirus infection; see Papillomaviruses Human rights

An epidemic of antiabortion violence in the United States (Grimes et al). 1991;165:1263-8 (Clin. opinion)

Human T-cell lymphocytic virus type 1; see HTLV-1

Comparison of humerus length with femur length in fetuses with Down syndrome (Rodis et al). 1991;165: 1051-6

Hydatidiform mole

Trophoblast from anembryonic pregnancy has both a maternal and a paternal contribution to its genome (Henderson et al), 1991;165:98-102

Hvdrocele

Fetal abdominoscrotal hydrocele (Sasidharan et al). 1991; 165:1353-5

Hydronephrosis

Congenital hydronephrosis: correlation of fetal ultrasonographic findings with infant outcome (Corteville et al). 1991;165:384-8

Renal pelvicalyceal dilation in antepartum pyelonephritis: ultrasonographic findings (Twickler et al). 1991;165: 1115-9

Hydrops fetalis

Hydrops fetalis in the McKusick-Kaufman syndrome: a case report (Rosen and Bocian). 1991;165:102-3

Management of fetal hemolytic disease by cordocentesis. I. Prediction of fetal anemia (Weiner et al). 1991;165:546-53

Management of fetal hemolytic disease by cordocentesis. II.
Outcome of treatment (Weiner et al). 1991;165:1302-7

- Report of fourteen cases of nonimmune hydrops fetalis in association with hemorrhagic endovasculitis of the placenta (Novak et al). 1991;165:945-50
- Steroid therapy for hydrops associated with antibody-mediated congenital heart block (Watson and Katz). 1991;165:553-4

Hydrops fetalis, animal

Elevated fetal plasma lactate produces polyhydramnios in the sheep (Powell and Brace). 1991;165:1595-607

Hydroxyandrostenedione

Is 11β-hydroxyandrostenedione a better marker of adrenal androgen excess than dehydroepiandrosterone sulfate? (Stanczyk et al). 1991;165:1839-42

3β-Hydroxysteroid dehydrogenase; see Hydroxysteroid dehydrogenases

Hydroxysteroid dehydrogenases

Adrenal and ovarian steroid hormone responses to gonadotropin-releasing hormone agonist treatment in polycystic ovary syndrome (Gonzalez et al). 1991;165:535-45

Hydroxyurea

Use of hydroxyurea in chronic myeloid leukemia during pregnancy: a case report (Patel et al). 1991;165:565-6

Hyperglycemia

The changing glycemic response to exercise during pregnancy (Clapp and Capeless). 1991;165:1678-83

Hyperglycemia, animal

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis (Finley and Norton). 1991;165:1661-6

Hyperinsulinemia

Absence of hyperinsulinemia in isoimmunized fetuses treated with intravascular transfusion (Socol et al). 1991;165:1737-40

Hypertension

- Antioxidant systems in normal pregnancy and in pregnancy-induced hypertension (Wisdom et al). 1991;165: 1701-4
- Concentration of digoxin-like immunoreactive substance in patients with preeclampsia and its relation to severity of pregnancy-induced hypertension (Kaminski and Rechberger). 1991;165:733-6
- The effect of maternal hemodynamics on fetal growth in hypertensive pregnancies (Easterling et al). 1991;165: 902-6
- High blood pressure in pregnancy (Iffy and Ganesh). 1991;165:236-7 (Letter)
- High plasma cellular fibronectin levels correlate with biochemical and clinical features of preeclampsia but cannot be attributed to hypertension alone (Taylor et al). 1991;165:895-901
- Indomethacin induces hypertensive crisis in preeclampsia irrespective of prior antihypertensive drug therapy (Mousavy) (Letter); (Schoenfeld) (Reply). 1991;165:1577
- Magnesium sulfate versus phenytoin for seizure prophylaxis in pregnancy-induced hypertension (Appleton et al). 1991;165:907-13
- The mechanism responsible for diminished neutrophil production in neonates delivered of women with pregnancy-induced hypertension (Koenig and Christensen). 1991;165:467-73
- Nifedipine pharmacokinetics and pharmacodynamics during the immediate postpartum period in patients with preeclampsia (Barton et al). 1991;165:951-4

- Patients with preeclampsia may be insensitive to atrial natriuretic factor (Goodlin). 1991;165:1161 (Letter)
- Potential role of endothelin-1 in normal and hypertensive pregnancies (Mastrogiannis et al). 1991;165: 1711-6
- The prevalence of autoantibodies during third-trimester pregnancy complicated by hypertension or idiopathic fetal growth retardation (Milliez et al). 1991;165:51-6
- Severe preeclampsia in the second trimester: recurrence risk and long-term prognosis (Sibai et al). 1991;165: 1408-12
- Transfer of aspirin across the perfused human placental cotyledon (Jacobson et al). 1991;165:939-44

Hypertension, animal

- Enhanced endothelium-derived relaxing factor activity in pregnant, spontaneously hypertensive rats (Ahokas et al). 1991;165:801-7
- Fetal hypertension induced by norepinephrine infusion and umbilical artery flow velocity waveforms in fetal sheep (van Huisseling et al). 1991;165:450-5

Hypertriglyceridemia

Hypertriglyceridemia in small-for-gestational-age fetuses (Bartnicki). 1991;165:1575 (Letter)

Hypoglycemic agents

Insignificant transfer of glyburide occurs across the human placenta (Elliott et al). 1991;165:807-12

Hyponatremia

Inappropriate secretion of antidiuretic hormone in Sheehan's syndrome: a rare cause of postpartum hyponatremia (Putterman et al). 1991;165:1330-3

Hypopituitarism

Inappropriate secretion of antidiuretic hormone in Shee-han's syndrome: a rare cause of postpartum hyponatremia (Putterman et al). 1991;165:1330-3

Hypoplastic left heart syndrome; see Heart defects, congenital

Hyporegenerative anemia; see Anemia

Hypotension

Postpartum preeclampsia-induced shock and death: a report of three cases (Kalur et al). 1991;165:1362-8

Hypothalamus, animal

The effect of hypothalamic lesions on the length of gestation in fetal sheep (Gluckman et al). 1991;165:1464-8

Hypotonic solutions

Fetal cardiovascular and fluid responses to maternal volume loading with lactated Ringer's or hypotonic solutions (Powers and Brace). 1991;165:1504-15

Hypoxia; see Anoxia

Hysterectomy

- The Cherney incision for gynecologic cancer (Brand) (Letter); (Helmkamp) (Reply). 1991;165:235
- Correlation between sexual abuse and somatization in women with somatic and nonsomatic chronic pelvic pain (Reiter et al). 1991;165:104-9
- Elective versus emergency cesarean hysterectomy cases in a residency program setting: a review of 129 cases from 1984 to 1988 (Gonsoulin et al). 1991;165:91-4

Hysterectomy, vaginal

Transvaginal removal of ovaries with endoloop sutures at the time of transvaginal hysterectomy (Hoffman). 1991;165:407-8

Hysteroscopy

A plea for early diagnosis of fallopian tube carcinoma: Can hysteroscopy be of use? (Sholapurkar). 1991;165:483 (Letter)

Hysteroscopy-cont'd

Vasopressin and operative hysteroscopy in the management of delayed postabortion and postpartum bleeding (Townsend et al). 1991;165:616-8

Ι

Idiometric assay

Idiometric assay, the third way: a noncompetitive immunoassay for small molecules (Barnard and Kohen). 1991;165:1997-2000

Idiopathic fetal growth retardation; see Fetal growth retardation

Iloprost

Reduction of primary posttraumatic adhesion formation with the prostacyclin analog iloprost in a rodent model (Steinleitner et al). 1991;165:1817-20

Immunity, natural

The effects of betamethasone on maternal cellular resistance to infection (Cunningham and Evans). 1991; 165:610-5

Immunoassay

Idiometric assay, the third way: a noncompetitive immunoassay for small molecules (Barnard and Kohen). 1991;165:1997-2000

Immunologic diseases

Prolonged exposure to wood preservatives induces endocrine and immunologic disorders in women (Gerhard et al). 1991;165:487-8 (Letter)

Immunopurification

Expression of extracellular matrix—degrading metalloproteinases by cultured human cytotrophoblast cells: effects of cell adhesion and immunopurification (Bischof et al). 1991;165:1791-801

Implantation of ovum; see Ovum implantation

In utero surgery; see Surgery

In vitro fertilization; see Fertilization in vitro India

Center for Research, Education, Service and Training's fertility education program for youth (Mascarenhas). 1991;165:2070 (Abstract)

The modified mucus method in India (Dorairaj). 1991;165:2066-7

Natural family planning through the health sector in India (Mascarenhas). 1991;165:2073 (Abstract)

Indomethacin

Combination antibiotics and indomethacin in idiopathic preterm labor: a randomized double-blind clinical trial (Newton et al). 1991;165:1753-9

Indomethacin induces hypertensive crisis in preeclampsia irrespective of prior antihypertensive drug therapy (Mousavy) (Letter); (Schoenfeld) (Reply). 1991;165:1577

Induction of labor; see Labor, induced Infant, low birth weight

Postnatal outcome depends on prenatal history (Giorlandino) (Letter); (Lipper) (Reply). 1991;165:1159-60

Prediction of survival of infants weighing <800 grams at birth: errors in the application of multivariate statistical techniques (Ales) (Letter); (Lipper) (Reply). 1991;165: 489-3

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14

Psychosocial support for maternal stress during pregnancy: effect on birth weight (Rothberg and Lits). 1991;165:403-7

Shoulder dystocia: Should the fetus weighing ≥4000 grams be delivered by cesarean section? (Langer et al). 1991;165:831-7

Infant, newborn

Human T-cell lymphotropic virus type I infection and pregnancy: a case-control study and 12-month follow-up of 135 women and their infants (Ville et al). 1991;165:1438-43

Neurologic versus behavioral neonatal assessment after birth asphyxia (Amiel-Tison and Stewart) (Letter); (Low) (Reply). 1991;165:1157

Infant, newborn, diseases

The mechanism responsible for diminished neutrophil production in neonates delivered of women with pregnancy-induced hypertension (Koenig and Christensen). 1991; 165:467-73

Infant, premature

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14

Quantification of cervical change: relationship to preterm delivery in the multifetal gestation (Newman et al). 1991;165:264-71

Infant, small for gestational age

Hypertriglyceridemia in small-for-gestational-age fetuses (Bartnicki). 1991;165:1575 (Letter)

Infant mortality

Double jeopardy: twin infant mortality in the United States, 1983 and 1984 (Fowler et al). 1991;165:15-22

A five-year statewide experience with congenital diaphragmatic hernia (Wenstrom et al). 1991;165:838-42

Microbiologic causes and neonatal outcomes associated with chorioamnion infection (Hillier et al). 1991;165:955-61

The pathology of maternal mortality (Shanklin et al). 1991;165:1126-55

Prediction of survival of infants weighing <800 grams at birth: errors in the application of multivariate statistical techniques (Ales) (Letter); (Lipper) (Reply). 1991;165: 482-3

Quantification of cervical change: relationship to preterm delivery in the multifetal gestation (Newman et al). 1991;165:264-71

The second stage of labor: factors influencing duration (Piper et al). 1991;165:976-9

Uterine activity after preterm premature rupture of the membranes (Campbell et al). 1991;165:422-5

Infant outcome; see Pregnancy outcome Infection

Adjunctive clindamycin therapy for preterm labor: results of a double-blind, placebo-controlled trial (McGregor et al). 1991;165:867-75

Amniotic fluid white blood cell count: a rapid and simple test to diagnose microbial invasion of the amniotic cavity and predict preterm delivery (Romero et al). 1991; 165:821-30

Correlation of amniotic fluid glucose concentration and intraamniotic infection in patients with preterm labor or premature rupture of membranes (Gauthier et al). 1991;165:1105-10

The effects of betamethasone on maternal cellular resistance to infection (Cunningham and Evans). 1991; 165:610-5

The enhanced production of placental interleukin-1 during labor and intrauterine infection (Taniguchi et al). 1991;165:131-7

Ethics in medical studies with human subjects (Sherer and Abramowicz) (Letter); (Goldstein and Zimmer) (Reply). 1991;165:1895-6

Microbiologic causes and neonatal outcomes associated with chorioamnion infection (Hillier et al). 1991;165:955-61

Neutrophil attractant/activating peptide-1/interleukin-8 in term and preterm parturition (Romero et al). 1991;165:813-20

Prenatal diagnosis of fetal cytomegalovirus infection (Lynch et al). 1991;165:714-8

Preterm premature rupture of membranes: detection of infection (Roussis et al). 1991;165:1099-104

Infertility, female

Infertility and eating disorders (McCluskey et al) (Letter); (Stewart) (Reply). 1991;165:1576-7

Infertility, male

Evidence for a partial deletion in the androgen receptor gene in a phenotypic male with azoospermia (Akin et al). 1991;165:1891-4

Infusion pumps

Administration of heparin by subcutaneous infusion with a programmable pump (Floyd et al). 1991;165:931-3

Inhibin

Inhibin subunits in human placenta: localization and messenger ribonucleic acid levels during pregnancy (Petraglia et al). 1991;165:750-8

Inhibition of prostaglandin; see Prostaglandin antagonists Instruction of patient; see Patient education Insulin

Absence of hyperinsulinemia in isoimmunized fetuses treated with intravascular transfusion (Socol et al). 1991;165:1737-40

Longitudinal changes in insulin release and insulin resistance in nonobese pregnant women (Catalano et al). 1991;165:1667-72

Specific binding sites for insulin and insulin-like growth factor I in human endometrial cancer (Nagamani et al). 1991;165:1865-71

Insulin-like growth factor I

Specific binding sites for insulin and insulin-like growth factor I in human endometrial cancer (Nagamani et al). 1991;165:1865-71

Insulin resistance

Polycystic ovary syndrome and the androgen-insulin connection (Nader). 1991;165:346-8 (Clin. opinion)

Postbinding insulin resistance around parturition in the isolated rat epitrochlearis muscle (Toyoda et al). 1991;165:1475-80

Interferon, alpha, recombinant

Vulvovaginal human papillomavirus infections: clinical implications and management (Hatch). 1991;165:1183-8

Interferon alpha; see Interferon type I

Interferon type I

Combined interferon alfa and doxorubicin in the treatment of advanced cervical cancer (Welander et al). 1991;165:284-91

Interleukin-1

The effect of interleukin-1 on adhesion formation in the rat (Hershlag et al). 1991;165:771-4

The enhanced production of placental interleukin-I during labor and intrauterine infection (Taniguchi et al). 1991;165:131-7

Increased inducibility of inflammatory mediators from peripheral blood mononuclear cells of women with salpingitis (Witkin et al). 1991;165:719-23

Systemic administration of interleukin-1 induces preterm parturition in mice (Romero et al). 1991;165:969-71

Tumor necrosis factor-α and interleukin-1β production by human fetal Kupffer cells (Kutteh et al). 1991;165:112-20

Interleukin-1 beta; see Interleukin-1 Interleukin-2

Increased progesterone concentrations are necessary to suppress interleukin-2-activated human mononuclear cell cytotoxicity (Feinberg et al). 1991;165: 1872-6

Interleukin-2 receptors; see Receptors, interleukin-2 Interleukin-6

Increased inducibility of inflammatory mediators from peripheral blood mononuclear cells of women with salpingitis (Witkin et al). 1991;165:719-23

Interleukin-8

Neutrophil àttractant/activating peptide-1/interleukin-8 in term and preterm parturition (Romero et al). 1991; 165:813-20

International Federation for Family Life Promotion

The development of the International Federation for Family Life Promotion training guide (Martin). 1991;165:2072 (Abstract)

International Planned Parenthood Federation

International Planned Parenthood Federation's policy and support for periodic abstinence: rationale and future plans (Kopp). 1991;165:2075 (Abstract)

Intrauterine devices

Alternative estimates of ectopic pregnancy risks during contraception (Sivin) (Letter); (Franks and Beral) (Reply). 1991;165:1899-900

Nonbarrier contraceptives and vaginitis and vaginosis (Roy). 1991;165:1240-4

Intrauterine growth retardation; see Fetal growth retardation Intrauterine infection; see Pregnancy complications, infectious

Intrauterine transfusion; see Blood transfusion, intrauterine 16α -[125 I]iodo- 17β -estradiol; see Radioiodoestradiol

Items

Items. 1991;165:242, 492, 786, 1162, 1578, 1948

Itraconazole

Fungal morphology after treatment with itraconazole as a single oral dose in experimental vaginal candidosis in rats (Jansen et al). 1991;165:1552-7

J

Jaundice, neonatal

Management of fetal hemolytic disease by cordocentesis. I. Prediction of fetal anemia (Weiner et al). 1991;165:546-53

Judaism

Multifetal pregnancy reduction and disposal of untransplanted embryos in contemporary Jewish law and ethics (Grazi and Wolowelsky). 1991;165:1268-71 (Clin. opinion)

jun-B; see Proto-oncogenes

K

Karyotyping

The association between fetal karyotype and mean corpuscular volume (Sipes et al). 1991;165:1371-6

Kegel exercise; see Exercise

Kenya

Natural family planning: national program development in Kenya (Wahome and Mwaulu). 1991;165:2073 (Abstract)

Kidney, abnormalities

Renal agenesis in association with malformation of the female genital tract (Acién et al). 1991;165:1368-70

Kidney, animal

Role of endogenous atrial natriuretic factor in the regulation of fetal cardiovascular and renal function (Cheung). 1991;165:1558-67

Killer cells, natural

Natural killer cell cytotoxicity to herpes simplex virus-1—infected cells is not altered by pregnancy (Eriksen et al). 1991;165:965-8

Kupffer cells

Tumor necrosis factor-α and interleukin-1β production by human fetal Kupffer cells (Kutteh et al). 1991;165:112-20

L

Labor

- Case report of myocardial infarction in labor (Menegakis and Amstey). 1991;165:1383-4
- Computerized analysis of episodic changes in fetal heart rate variation in early labor (Dawes et al). 1991;165: 618-24
- Do catechol estrogens participate in the initiation of labor? (Biswas et al). 1991;165:984-7
- The enhanced production of placental interleukin-1 during labor and intrauterine infection (Taniguchi et al). 1991;165:131-7
- Fetal movement during labor (Reddy et al). 1991;165:1073-6
- Intrapartum course of fetuses with isolated hypoplastic left heart syndrome (Jackson et al). 1991;165:1068-72
- Intrapartum ultrasonographic estimates of fetal weight by the house staff (Platek et al). 1991;165:842-5
- Oxytocin secretion and human parturition: pulse frequency and duration increase during spontaneous labor in women (Fuchs et al). 1991;165:1515-23
- Prophylactic amnioinfusion as a treatment for oligohydramnios in laboring patients: a prospective, randomized trial (Schrimmer et al). 1991;165:972-5
- Qualitative evaluation of uterine contractions recorded by a double guard-ring tocodynamometer (Shinmoto et al). 1991;165:1282-6

Labor, animal

- Bilateral destruction of the fetal paraventricular nuclei prolongs gestation in sheep (McDonald and Nathanielsz). 1991;165:764-70
- Postbinding insulin resistance around parturition in the isolated rat epitrochlearis muscle (Toyoda et al). 1991; 165:1475-80

Labor, induced

- Fetal breathing movements before oxytocin induction in prolonged pregnancies (Schreyer et al). 1991;165:577-81
- Maturation of the uterine cervix by repeated intracervical instillation of prostaglandin E₂ (Milliez et al). 1991;165:523-8
- Patterns of uterine activity after intravaginal prostaglandin E₂ during preinduction cervical ripening (Miller et al). 1991;165:1006-9
- A prospective study of two dosing regimens of oxytocin for the induction of labor in patients with unfavorable cervices (Satin et al). 1991;165:980-4

- A randomized, double-blind trial of prostaglandin E₂ gel for cervical ripening and meta-analysis (Owen et al). 1991;165:991-6
- Uterine and fetal Doppler flow changes after intravaginal prostaglandin E₂ therapy for cervical ripening (Rayburn et al). 1991;165:125-6
- Uterine rupture at term pregnancy with the use of intracervical prostaglandin E₂ gel for induction of labor (Maymon et al). 1991;165:368-70

Labor, induced, animal

- Inhibition of oxytocin-induced uterine contractions by an oxytocin antagonist in the pregnant baboon (Wilson et al). 1991;165:456-60
- The progesterone antagonist onapristone increases the effectiveness of oxytocin to produce delivery without changing the myometrial oxytocin receptor concentrations (Chwalisz et al). 1991;165:1760-70
- Systemic administration of interleukin-1 induces preterm parturition in mice (Romero et al). 1991;165:969-71

Labor, premature

- Acute cutaneous vasculitis associated with prolonged intravenous ritodrine hydrochloride therapy (Bosnyak et al). 1991;165:427-8
- Adjunctive clindamycin therapy for preterm labor: results of a double-blind, placebo-controlled trial (McGregor et al). 1991;165:867-75
- Amniotic fluid white blood cell count: a rapid and simple test to diagnose microbial invasion of the amniotic cavity and predict preterm delivery (Romero et al). 1991; 165:821-30
- A case report of massive vulvar edema during tocolysis of preterm labor (Brittain et al). 1991;165:420-2
- Combination antibiotics and indomethacin in idiopathic preterm labor: a randomized double-blind clinical trial (Newton et al). 1991;165:1753-9
- Correlation of amniotic fluid glucose concentration and intraamniotic infection in patients with preterm labor or premature rupture of membranes (Gauthier et al). 1991;165:1105-10
- Multicenter randomized clinical trial of home uterine activity monitoring for detection of preterm labor (Mou et al). 1991;165:858-66
- Myocardial necrosis in a newborn after long-term maternal subcutaneous terbutaline infusion for suppression of preterm labor (Fletcher et al). 1991;165:1401-4
- Neutrophil attractant/activating peptide-1/interleukin-8 in term and preterm parturition (Romero et al). 1991;165:813-20
- Oral tocolysis with magnesium chloride: a randomized controlled prospective clinical trial (Ricci et al). 1991;165:603-10
- Placental pathologic findings in preterm birth (Salafia et al). 1991;165:934-8. 1991;165:1903 (Correction)
- Prognostic factors and complication rates for cervical cerclage: a review of 482 cases (Treadwell et al). 1991;165:555-8
- Quantification of cervical change: relationship to preterm delivery in the multifetal gestation (Newman et al). 1991;165:264-71
- Spontaneous preterm birth: a case-control study (de Haas et al). 1991;165:1290-6
- Untreated luteal phase deficiency as another possible risk factor for preterm delivery (Check and Lee) (Letter); (McGregor and French) (Reply). 1991;165: 485-6

Volume 165 . Subject index 1953 Number 6, Part 1

Labor, premature, animal

Inhibition of oxytocin-induced uterine contractions by an oxytocin antagonist in the pregnant baboon (Wilson et al). 1991;165:456-60

Systemic administration of interleukin-1 induces preterm parturition in mice (Romero et al). 1991;165:969-71

Labor complications

Appropriateness of intrapartum fetal heart rate management and risk of cerebral palsy (Melone et al). 1991;165:272-7

Labor onset, animal

Forward shift in the initiation of the nocturnal estradiol surge in the pregnant baboon: Is this the genesis of labor? (Wilson et al). 1991;165:1487-98

Labor presentation

One-blade rotation of a persistent posterior vertex (Escamilla and Carlan). 1991;165:373-4

Twin delivery: influence of the presentation and method of delivery on the second twin (Adam et al). 1991;165: 23-7

Labor stage, first

Patterns of uterine activity after intravaginal prostaglandin E₂ during preinduction cervical ripening (Miller et al). 1991;165:1006-9

A randomized, double-blind trial of prostaglandin $\rm E_2$ gel for cervical ripening and meta-analysis (Owen et al). 1991;165:991-6

Labor stage, second

The second stage of labor: factors influencing duration (Piper et al). 1991;165:976-9

Lactates

Elevated fetal plasma lactate produces polyhydramnios in the sheep (Powell and Brace). 1991;165:1595-607

Lactational amenorrhea

Is the lactational amenorrhea method a part of natural family planning? Biology and policy (Gross). 1991;165:2014-

Natural family planning: current knowledge and new strategies for the 1990s—Session III: discussion and recommendations (Parenteau-Carreau and Collins). 1991;165: 2045

Natural family planning: looking ahead (Queenan and Moghissi). 1991;165:1979-80

The natural family planning—lactational amenorrhea method interface: observations from a prospective study of breastfeeding users of natural family planning (Kennedy et al). 1991;165:2020-6

Overview and summary: the interface of breastfeeding, natural family planning, and the lactational amenorrhea method (Labbok and Howie). 1991;165:2013-4

Ovulation method use during breastfeeding: Is there increased risk of unplanned pregnancy? (Labbok et al). 1991;165:2031-6

The promotion of exclusive breastfeeding and the lactational amenorrhea method in natural family planning programs (Kennedy). 1991;165:2076 (Abstract)

Santiago Breastfeeding Promotion Program: preliminary results of an intervention study (Pérez and Valdés). 1991;165:2039-44

Lactobacillus

Cytolytic vaginosis (Cibley and Cibley). 1991;165:1245-9

Laparoelytrotomy

Laparoelytrotomy: abdominal delivery without uterine incision (Isik and Gülmezoğlu). 1991;165:781 (Letter)

Laparoscopy; see Peritoneoscopy

Laparotomy

Prognostic value of CA 125 and neopterin in women with ovarian cancer undergoing second-look laparotomy (Fuith et al). 1991;165:779 (Letter)

Laser surgery

Incidental appendectomy during videolaseroscopy (Nezhat and Nezhat). 1991;165:559-64

Laser vaporization of grade 3 vaginal intraepithelial neoplasia (Hoffman et al). 1991;165:1342-4

Videolaseroscopy for oophorectomy (Nezhat et al). 1991;165:1323-30

Vulvovaginal human papillomavirus infections: clinical implications and management (Hatch). 1991;165:1183-8

Lead

The three most common occupational exposures reported by pregnant women: an update (Bentur and Koren). 1991;165:429-37 (Curr. dev.)

Legislation

Communicating with developing country policymakers: the case for natural family planning (Murphy). 1991;165: 2075 (Abstract)

Gaining policy support for natural family planning (Jennings). 1991;165:2074 (Abstract)

International Planned Parenthood Federation's policy and support for periodic abstinence: rationale and future plans (Kopp). 1991;165:2075 (Abstract)

Natural family planning: Agency for International Development policy considerations (Clark and Spieler). 1991;165:2074 (Abstract)

Natural family planning through the health sector in Brazil (Sogayar). 1991;165:2073 (Abstract)

Policies and support for natural family planning: rationales and future plans (Donayre). 1991;165:2075 (Abstract)

Policy issues in natural family planning (Jennings et al). 1991;165:2074-5 (Abstract)

From policy to norms to services: developing a consensus for natural family planning (Skipp). 1991;165:2075 (Abstract)

Political and practical issues in the implementation of operations research studies in natural family planning (Townsend and Vernon). 1991;165:2078 (Abstract)

Understanding policy and the policy-making process: considerations for initiating policy interest (Rodriguez-Garcia). 1991;165:2075 (Abstract)

World Health Organization's policy considerations in natural family planning (Mehra). 1991;165:2075 (Abstract)

Letters

Letters. 1991;165:235-41, 482-9, 779-85, 1156-61, 1575-7, 1939-45

Leukemia, myeloid, chronic

Use of hydroxyurea in chronic myeloid leukemia during pregnancy: a case report (Patel et al). 1991;165:565-6

Leukocytes, mononuclear

Increased progesterone concentrations are necessary to suppress interleukin-2-activated human mononuclear cell cytotoxicity (Feinberg et al). 1991;165:1872-6

Leukotrienes

Effects of leukotrienes in the placental vasculature (Sullivan et al) (Letter); (Walsh) (Reply). 1991;165:1575-6

LH

The gonadotropin-releasing hormone antagonist (Nal-Glu) acutely blocks the luteinizing hormone surge but allows for resumption of folliculogenesis in normal women (Ditkoff et al). 1991;165:1811-7

1954 Subject index

December 1991

Am | Obstet Gynecol

Liberia

Evaluation of natural family planning programs in Liberia and Zambia (Kambic et al). 1991;165:2078 (Abstract)

Factors related to autonomy and discontinuation of use of natural family planning for women in Liberia and Zambia (Kambic and Gray). 1991;165:2060-2

Light-reflection rheography; see Plethysmography, impedance

Lipid peroxides

The imbalance between thromboxane and prostacyclin in preeclampsia is associated with an imbalance between lipid peroxides and vitamin E in maternal blood (Wang et al). 1991;165:1695-700

Maternal levels of prostacyclin, thromboxane, vitamin E, and lipid peroxides throughout normal pregnancy (Wang et al). 1991;165:1690-4

Lipids

Changes in lipids and lipoproteins with long-term estrogen deficiency and hormone replacement therapy (Gambrell and Teran). 1991;165:307-17

Does intensive glycemic control in diabetic pregnancies result in normalization of other metabolic fuels? (Reece et al). 1991;165:126-30

Lipoproteins

Changes in lipids and lipoproteins with long-term estrogen deficiency and hormone replacement therapy (Gambrell and Teran). 1991;165:307-17

Liver

Hemostatic wrapping of ruptured liver in two postpartum patients (Rittenberry et al). 1991;165:705-7

Local anesthesia; see Anesthesia, local

Low birth weight; see Infant, low birth weight

Loxocelism; see Spider venoms

Luteal phase

Untreated luteal phase deficiency as another possible risk factor for preterm delivery (Check and Lee) (Letter); (McGregor and French) (Reply). 1991;165:485-6

Luteinizing hormone; see LH

Lymph, animal

Left thoracic duct lymph flow responses to angiotensin II or atrial natriuretic factor infusion in the ovine fetus (Brace and Andres). 1991;165:1607-13

Lymphatic system

Histologic study of endometriosis and examination of lymphatic drainage in and from the uterus (Ueki). 1991;165:201-9 (Symposium)

Lymphocytes

Lymphocytes stimulate progesterone production by cultured human granulosa luteal cells (Emi et al). 1991;165:1469-74

M

Macrophage colony-stimulating factor

Increased serum levels of macrophage colony-stimulating factor in ovarian cancer (Xu et al). 1991;165:1356-62

Macrophages

Effects of peritoneal macrophages from patients with endometriosis on the proliferation of endometrial carcinoma cell line ECC-1 (Zhang et al). 1991;165:1842-6

Magnesium

Effects of magnesium and terbutaline on contractility and K+ uptake in isolated human uterine muscle (Skajaa et al). 1991;165:1543-51

Magnesium chloride

Oral tocolysis with magnesium chloride: a randomized con-

trolled prospective clinical trial (Ricci et al). 1991;165:603-10

Magnesium sulfate

In vivo and in vitro effects of magnesium sulfate in the cerebrovascular bed of the goat (Perales et al). 1991;165:1534-8

Magnesium sulfate versus phenytoin for seizure prophylaxis in pregnancy-induced hypertension (Appleton et al). 1991:165:907-13

Major basic protein

Association of immunoreactive eosinophil major basic protein with placental septa and cysts (Wasmoen et al). 1991;165:416-20

Malpractice

Analysis of 500 obstetric and gynecologic malpractice claims: causes and prevention (Ward). 1991;165:298-306 Costs and benefits of examining all placentas (Mittal) (Letter); (Salafia and Vintzileos) (Reply). 1991;165:235

Marijuana; see Cannabis

Marriage

Toward better marriages through natural family planning (Osmund-Ruiz). 1991;165:2076 (Abstract)

Mass media

Lessons learned from a mass-media campaign in Peru (Tagliabue). 1991;165:2070 (Abstract)

Mass screening

Adverse psychologic consequences of positive cytologic cervical screening (Lerman et al). 1991;165:658-62

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-7

Endometrial morphology in asymptomatic postmenopausal women (Archer et al). 1991;165:317-22

Incidence and prevalence of human immunodeficiency virus infection in a prenatal population undergoing routine voluntary human immunodeficiency virus screening, July 1987 to June 1990 (Lindsay et al). 1991;165: 961-4

Ovarian cancer screening: potential effect on mortality (Westhoff and Randall). 1991;165:502-5

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14

Prospective evaluation of maternal serum human chorionic gonadotropin levels in 3428 pregnancies (Bogart et al). 1991;165:663-7

Screening in ovarian cancer (Creasman and DiSaia). 1991;165:7-10 (Clin. opinion)

Screening recommendations for gestational diabetes mellitus (Cousins et al). 1991;165:493-6 (Clin. opinion)

Value of high and low maternal serum α-fetoprotein levels in screening singleton pregnancies (Minaretzis and Tsionou) (Letter); (Milunsky) (Reply). 1991;165:780

Maternal behavior

Medication in early pregnancy: prevalence of use and relationship to maternal characteristics (Buitendijk and Bracken). 1991;165:33-40

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14

Maternal-fetal bonding; see Mother-child relations Maternal-fetal exchange

Endothelin-1-induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation (Myatt et al). 1991;165:1717-22

Volume 165 ' Number 6, Part 1

Insignificant transfer of glyburide occurs across the human placenta (Elliott et al). 1991;165:807-12

Transfer of aspirin across the perfused human placental cotyledon (Jacobson et al). 1991;165:939-44

Maternal mortality

Elective versus emergency cesarean hysterectomy cases in a residency program setting: a review of 129 cases from 1984 to 1988 (Gonsoulin et al). 1991;165:91-4

The pathology of maternal mortality (Shanklin et al). 1991;165:1126-55

Postpartum preeclampsia-induced shock and death: a report of three cases (Kalur et al). 1991;165:1362-8

Maternal welfare

Psychosocial support for maternal stress during pregnancy: effect on birth weight (Rothberg and Lits). 1991;165:403-7

Mauritius

The 1991 Mauritius contraceptive prevalence study (Chen et al). 1991;165:2077 (Abstract)

McKusick-Kaufman syndrome; see Chromosome abnormalities

Mean corpuscular volume; see Blood volume Meclofenamic acid

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep (Arnold-Aldea et al). 1991;165:185-90

Meconium

"Meconiumcrit" and birth asphyxia (Trimmer and Gilstrap). 1991;165:1010-3

Medical history taking

Identifying pregnant women who drink alcoholic beverages (Mullen et al). 1991;165:1429-30

Medication; see Drugs

Meiosis

The effects of electric field-mediated transfer of nonpermeable molecules of meiosis, fertilization, and early embryo development (Douglas et al). 1991;165: 1480-6

Melatonin

Circadian myometrial and endocrine rhythms in the pregnant rhesus macaque: effects of constant light and timed melatonin infusion (Matsumoto et al). 1991;165:1777-84

Menopause

Endometrial morphology in asymptomatic postmenopausal women (Archer et al). 1991;165:317-22

Menstrual cycle

The effect of the menstrual cycle and of decompression stress on arachidonic acid-induced platelet aggregation and on intrinsic platelet thromboxane production in women compared with men (Markham et al). 1991; 165:1821-9

Measurement of human epidermal growth factor receptor in the endometrium during the menstrual cycle (Troche et al). 1991;165:1499-503

Simultaneous measurements of prostacyclin and thromboxane metabolites during the menstrual cycle (Presser et al). 1991;165:647-51

Use of the home ovarian monitor in pregnancy avoidance (Brown et al). 1991;165:2007-11

Menstruation disorders

Peritoneal endometriosis: endometrial tissue implantation as its primary etiologic mechanism (Ishimaru and Masuzaki). 1991;165:210-4 (Symposium)

Mental retardation

Recombinant 8 syndrome: the pool of Hispanic pericentric

inversion 8 carriers expands numerically and geographically (Izquierdo et al). 1991;165:1419-22

Metabolic clearance rate

The metabolic clearance rate of epinephrine in the fetus of the diabetic ewe (Dickinson et al). 1991;165:1655-60

Metalloproteinases

Expression of extracellular matrix—degrading metalloproteinases by cultured human cytotrophoblast cells: effects of cell adhesion and immunopurification (Bischof et al). 1991;165:1791-801

Metaplasia

A reappraisal of the coelomic metaplasia theory by reviewing endometriosis occurring in unusual sites and instances (Suginami). 1991;165:214-8 (Symposium)

Secondary müllerian system and endometriosis (Fujii). 1991;165:219-25 (Symposium)

Metronidazole

Bacterial vaginosis: current review with indications for asymptomatic therapy (Thomason et al). 1991;165:1210-7.

Trichomoniasis: trends in diagnosis and management (Lossick and Kent). 1991;165:1217-22

Microbial invasion; see Infection

Micromanipulation

Partial dissection of the zona pellucida of frozen-thawed human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Mifepristone

Daily administration of the progesterone antagonist RU 486 prevents implantation in the cycling guinea pig (Batista et al). 1991;165:82-6

Milk, human

CA 125 in breast milk (Fuith) (Letter); (O'Brien) (Reply). 1991;165:1158-9

Miscarriage; see Abortion

Mitochondria, animal

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis (Finley and Norton). 1991;165:1661-6

Monitoring, ambulatory electrocardiographic; see Electrocardiography, ambulatory

Monocytes

Increased inducibility of inflammatory mediators from peripheral blood mononuclear cells of women with salpingitis (Witkin et al). 1991;165:719-23

Mononuclear cells; see Leukocytes, mononuclear

Mortality; see also Fetal death; Infant mortality; Maternal mortality

Ovarian cancer screening: potential effect on mortality (Westhoff and Randall). 1991;165:502-5

Mother-child relations

The effect of fetal movement counting on maternal attachment to fetus (Mikhail et al). 1991;165:988-91

Impact of prenatal testing on maternal-fetal bonding: chorionic villus sampling versus amniocentesis (Caccia et al). 1991;165:1122-5

Mouth mucosa, animal

Oral-nasal membranes are not the major route for fetal absorption of amniotic fluid arginine vasopressin (Gilbert et al). 1991;165:1614-20

Müllerian duct

Secondary müllerian system and endometriosis (Fujii). 1991;165:219-25 (Symposium)

Müllerian inhibiting substance

Cellular localization of müllerian inhibiting substance messenger ribonucleic acid during human ovarian follicular development (Whitman and Pantazis). 1991;165:1881-6

Multivariate analysis

Prediction of survival of infants weighing <800 grams at birth: errors in the application of multivariate statistical techniques (Ales) (Letter); (Lipper) (Reply). 1991;165: 482-3

Muscle, smooth, vascular

Angiotensin II vascular smooth-muscle receptors are not down-regulated in near-term pregnant sheep (Mackanjee et al). 1991;165:1641-8

Muscles

Splitting hairs about splitting muscles (Sutton) (Letter); (Helmkamp) (Reply). 1991;165:1575

Muscles, animal

Postbinding insulin resistance around parturition in the isolated rat epitrochlearis muscle (Toyoda et al). 1991;165:1475-80

Muscular dystrophy

In utero fetal muscle biopsy for the diagnosis of Duchenne muscular dystrophy (Evans et al). 1991;165:728-32

Mycotic infections

Mycotic vulvovaginitis: a broad overview (Horowitz). 1991;165:1188-92

Vulvovaginitis: the role of patient compliance in treatment success (Nixon). 1991;165:1207-9

Myocardial diseases

Myocardial necrosis in a newborn after long-term maternal subcutaneous terbutaline infusion for suppression of preterm labor (Fletcher et al). 1991;165:1401-4

Myocardial infarction

Acute myocardial infarction associated with prostaglandin E₂ (Meyer et al). 1991;165:359-60

Case report of myocardial infarction in labor (Menegakis and Amstey). 1991;165:1383-4

Myocardium, ultrastructure

Endomyocardial ultrastructural findings in preeclampsia (Barton et al). 1991;165:389-91

Myoma

Vasopressin pack for treatment of bleeding after myoma resection (Townsend). 1991;165:1405-7

Myometrium

Effects of magnesium and terbutaline on contractility and K⁺ uptake in isolated human uterine muscle (Skajaa et al). 1991;165:1543-51

Myometrium, animal

Circadian myometrial and endocrine rhythms in the pregnant rhesus macaque: effects of constant light and timed melatonin infusion (Matsumoto et al). 1991;165:1777-84

The progesterone antagonist onapristone increases the effectiveness of oxytocin to produce delivery without changing the myometrial oxytocin receptor concentrations (Chwalisz et al). 1991;165:1760-70

N

N¹-acetylspermine

Failure to verify high activities of polyamine oxidase in pregnancy serum (Kumazawa et al). 1991;165:1457-8

Nal-Glu

Comparison of intermittent and continuous use of a gonadotropin-releasing hormone antagonist (Nal-Glu) in in vitro fertilization cycles: a preliminary report (Cassidenti et al). 1991;165:1806-10

The gonadotropin-releasing hormone antagonist (Nal-Glu) acutely blocks the luteinizing hormone surge but allows for resumption of folliculogenesis in normal women (Ditkoff et al). 1991;165:1811-7

Narcotics

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-7

Nasal mucosa, animal

Oral-nasal membranes are not the major route for fetal absorption of amniotic fluid arginine vasopressin (Gilbert et al). 1991;165:1614-20

Natriuretic peptides, atrial

Aprotinin blocks the binding of pro atrial natriuretic peptides 1 to 30, 31 to 67, and 99 to 126 in human placental membranes (Vesely). 1991;165:567-73

Atrial natriuretic factor responses to volume expansion in pregnant and nonpregnant sheep (Bennett and Rose). 1991;165:1627-34

Atrial natriuretic peptide: A vasodilator of the fetoplacental circulation? (Kingdom et al). 1991;165:791-800

Effects of angiotensin II on atrial natriuretic peptide in pregnancy (Didden et al). 1991;165:692-5

Fetal and maternal plasma atrial natriuretic factor responses to angiotensin II infusion (Ross et al). 1991;165:1635-41

Hemorrhage-induced reductions in plasma atrial natriuretic factor in the ovine fetus (Cheung and Brace). 1991;165:474-81

Left thoracic duct lymph flow responses to angiotensin II or atrial natriuretic factor infusion in the ovine fetus (Brace and Andres). 1991;165:1607-13

Patients with preeclampsia may be insensitive to atrial natriuretic factor (Goodlin). 1991;165:1161 (Letter)

Regulation of atrial natriuretic peptide release in pregnancy: responses to posture (Lowe et al). 1991;165:591-

Relaxation of the human uterine artery by atrial natriuretic peptide is independent of the endothelium (Bodelsson et al). 1991;165:483-4 (Letter)

Role of endogenous atrial natriuretic factor in the regulation of fetal cardiovascular and renal function (Cheung). 1991;165:1558-67

Natural family planning

Current status of operations research in natural family planning (Ricci and Seidman). 1991;165:2077 (Abstract)

Fetal outcome among pregnancies in natural family planning acceptors: an international cohort study (Simpson et al). 1991;165:1981-2

Operations research in natural family planning: strategies, issues, and research approaches (Ricci et al). 1991;165:2077-8 (Abstract)

Political and practical issues in the implementation of operations research studies in natural family planning (Townsend and Vernon). 1991;165:2078 (Abstract)

Session I. Major scientific issues in natural family planning: introduction (Queenan et al). 1991;165:1977-8

Using operations research to improve natural family planning program services, management, and policy (Wawer et al). 1991;165:2078 (Abstract)

Natural family planning, economics

- Budgeting and financial planning in natural family planning programs: in search of the perfect system (Pedersen). 1991;165:2074 (Abstract)
- Evaluation of natural family planning programs in Liberia and Zambia (Kambic et al). 1991;165:2078 (Abstract)
- Natural family planning program format effectiveness (Kramer). 1991;165:2078 (Abstract)
- Operations research in natural family planning: strategies, issues, and research approaches (Ricci et al). 1991;165:2077-8 (Abstract)
- XV. Roundtable discussions (Vogelsang). 1991;165:2075-6 (Abstract)
- Various forms of financial support for natural family planning teachers (Lanctôt). 1991;165:2076 (Abstract)

Natural family planning, education

- Adapting data systems of multimethod programs to incorporate natural family planning (Cuervo). 1991;165:2074 (Abstract)
- An American national experience: natural family planning serves under the auspices of the Roman Catholic Church (Notare). 1991;165:2073 (Abstract)
- Center for Research, Education, Service and Training's fertility education program for youth (Mascarenhas). 1991;165:2070 (Abstract)
- Client teaching materials for francophone Africa (Ecochard). 1991;165:2072 (Abstract)
- Competency-based approach to training and natural family planning instructor standards (Martin). 1991;165:2069 (Abstract)
- Creating a demand for scientific natural family planning: the Zambian experience (Tafira). 1991;165:2070 (Abstract)
- Current natural family planning programs and strategies for expanding service delivery: an introduction (Mejia and Solis). 1991;165:2072 (Abstract)
- The development of the International Federation for Family Life Promotion training guide (Martin). 1991;165:2072 (Abstract)
- Expanding natural family planning through vocational schools for women in Cote d'Ivoire (Rodriguez-Garcia). 1991;165:2073 (Abstract)
- Experiences and trends in natural family planning education and outreach (Rodriguez-Garcia et al). 1991;165:2070-1 (Abstract)
- Experiences in the field: Confederacao Nacional de Centros de Planejamento Natural da Familia, Brazil (Sogayar). 1991;165:2071 (Abstract)
- An experiential approach to training natural family planning trainers (Aumack). 1991;165:2069 (Abstract)
- Fertility education for young men (Burke). 1991;165:2071 (Abstract)
- The "Guide for Natural Family Planning Trainers" (Aumack). 1991;165:2072 (Abstract)
- Innovative approaches from population communication services: implications for natural family planning (Lozaré). 1991;165:2070 (Abstract)
- Introduction and overview of natural family planning training programs (Vogelsang). 1991;165:2069 (Abstract)
- Introduction of natural family planning information into multimethod materials for trainers (Lea and Murphy). 1991;165:2071 (Abstract)
- Issues in the development and dissemination of training and educational materials (Schaefer). 1991;165:2071 (Abstract)

- Lessons learned from a mass-media campaign in Peru (Tagliabue). 1991;165:2070 (Abstract)
- Materials development, testing, and evaluation: an overview (Zimmerman and Bartlett). 1991;165:2071 (Abstract)
- Materials development in Zambia: concept versus reality (Tafira). 1991;165:2071 (Abstract)
- Materials for the modified mucus method (Dorairaj). 1991;165:2072 (Abstract)
- Materials in the United States: an example from Los Angeles (Minervini). 1991;165:2072 (Abstract)
- Materials translation: Is that really what you want to say? (Bowen and Bowen). 1991;165:2071 (Abstract)
- The missing link—why natural family planning is still "the best kept secret" (Ek). 1991;165:2075 (Abstract)
- Natural family planning: national program development in Kenya (Wahome and Mwaulu). 1991;165:2073 (Abstract)
- Natural family planning in a family planning program (Kring). 1991;165:2072 (Abstract)
- Natural family planning through the health sector in India (Mascarenhas). 1991;165:2073 (Abstract)
- Natural family planning training issues and strategies for the 1990s (Aumack et al). 1991;165:2069 (Abstract)
- New approaches to expanding natural family planning (Skipp). 1991;165:2072 (Abstract)
- New directions for education and outreach in the 1990s (Rodriguez-Garcia). 1991;165:2070 (Abstract)
- A pilot study on teaching natural family planning in general practice (Clubb et al). 1991;165:2078 (Abstract)
- A pilot study on teaching natural family planning in general practice (Pyper). 1991;165:2076 (Abstract)
- Preparing instructors to educate diverse client populations: the impact of culture, religion, socioeconomic status, and educational levels (Mascarenhas). 1991;165:2069 (Abstract)
- Providing natural family planning counseling within a family planning clinic (Minervini). 1991;165:2076 (Abstract)
- Reaching new populations with natural family planning education (Mehra). 1991;165:2070 (Abstract)
- XV. Roundtable discussions (Vogelsang). 1991;165:2075-6
- Seeking opportunities for natural family planning expansion: the Serena experience (Parenteau-Carreau). 1991;165:2070 (Abstract)
- Service delivery part 1: current programs and strategies for expansion (Mejia et al). 1991;165:2072-3 (Abstract)
- Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cchort (Klaus and Kardatzke). 1991;165:2071 (Abstract)
- Training and educational materials (Schaefer et al). 1991;165:2071-2 (Abstract)
- Training and supervision from small natural family planning programs to national service delivery systems (Mwaulu). 1991;165:2069 (Abstract)
- Training evaluation: its impact on future instructor training, client education, and natural family planning services (Walter). 1991:165:2069 (Abstract)
- At what stage is natural family planning service delivery? (Klaus). 1991;165:2076 (Abstract)

Natural family planning, legislation

- Communicating with developing country policymakers: the case for natural family planning (Murphy). 1991; 165:2075 (Abstract)
- Gaining policy support for natural family planning (Jennings). 1991;165:2074 (Abstract)

Natural family planning, legislation-cont'd

- International Planned Parenthood Federation's policy and support for periodic abstinence: rationale and future plans (Kopp). 1991;165:2075 (Abstract)
- Natural family planning: Agency for International Development policy considerations (Clark and Spieler). 1991;165:2074 (Abstract)
- Natural family planning through the health sector in Brazil (Sogayar). 1991;165:2073 (Abstract)
- Policies and support for natural family planning: rationales and future plans (Donayre). 1991;165:2075 (Abstract)
- Policy issues in natural family planning (Jennings et al). 1991;165:2074-5 (Abstract)
- From policy to norms to services: developing a consensus for natural family planning (Skipp). 1991;165:2075 (Abstract)
- Political and practical issues in the implementation of operations research studies in natural family planning (Townsend and Vernon). 1991;165:2078 (Abstract)
- Understanding policy and the policy-making process: considerations for initiating policy interest (Rodriguez-Garcia). 1991;165:2075 (Abstract)
- World Health Organization's policy considerations in natural family planning (Mehra). 1991;165:2075 (Abstract)

Natural family planning, methods

- Breastfeeding: a natural method for child spacing (Howie). 1991;165:1990-1
- Efficacy of the symptothermal method of natural family planning in lactating women after the return of menses (Zinaman and Stevenson). 1991;165:2037-9
- The evolution of reference methods to monitor ovulation: How well do current markers perform? (Collins). 1991;165:1994-6
- The fertility awareness method: extent of use, potential, and research needs (Williamson). 1991;165:2076 (Abstract)
- Further analysis of contraceptive failure of the ovulation method (Trussell and Grummer-Strawn). 1991;165:2054-
- Human cervical mucus: research update (Katz). 1991; 165:1984-6
- Idiometric assay, the third way: a noncompetitive immunoassay for small molecules (Barnard and Kohen). 1991;165:1997-2000
- Is the lactational amenorrhea method a part of natural family planning? Biology and policy (Gross). 1991;165:2014-9
- Knowledge and use of periodic abstinence (Vaessen). 1991;165:2077 (Abstract)
- Making periodic abstinence more acceptable to natural family planning users (Uricchio). 1991;165:2075 (Abstract)
- The modified mucus method in India (Dorairaj). 1991;165:2066-7
- Natural family planning: current knowledge and new strategies for the 1990s—Session I: discussion and recommendations (Queenan and Moghissi). 1991;165: 1009
- Natural family planning: current knowledge and new strategies for the 1990s—Session II: discussion and recommendations. 1991;165:2012
- Natural family planning: current knowledge and new strategies for the 1990s—Session III: discussion and recommendations (Parenteau-Carreau and Collins). 1991;165: 2045
- Natural family planning and sex selection: Fact or fiction? (Gray). 1991;165:1982-4

- The natural family planning—lactational amenorrhea method interface: observations from a prospective study of breastfeeding users of natural family planning (Kennedy et al). 1991;165:2020-6
- Overview and issues in ovulation prediction (Zinaman and France). 1991;165:1993
- Overview and summary: the interface of breastfeeding, natural family planning, and the lactational amenorrhea method (Labbok and Howie). 1991;165:2013-4
- Ovulation method use during breastfeeding: Is there increased risk of unplanned pregnancy? (Labbok et al). 1991;165:2031-6
- A profile of successful versus unsuccessful ovulation method users: factors associated with unplanned pregnancy and nonadherence to the rules (Labbok et al). 1991;165:2077 (Abstract)
- The promotion of exclusive breastfeeding and the lactational amenorrhea method in natural family planning programs (Kennedy). 1991;165:2076 (Abstract)
- A prototype for ovulation detection: pros and cons (Lasley et al). 1991;165:2003-7
- XV. Roundtable discussions (Vogelsang). 1991;165:2075-6 (Abstract)
- Santiago Breastfeeding Promotion Program: preliminary results of an intervention study (Pérez and Valdés). 1991;165:2039-44
- Symptothermal and hormonal markers of potential fertility in climacteric women (Flynn et al). 1991;165: 1987-9
- Use of the home ovarian monitor in pregnancy avoidance (Brown et al). 1991;165:2008-11

Natural family planning, psychology

- Overview of social science and behavioral issues in natural family planning (Sharma and Spieler). 1991;165:2076 (Abstract)
- Psychosexual aspects of natural family planning as revealed in the World Health Organization multicenter trial of the ovulation method and the New Zealand continuation study (France). 1991;165:2077 (Abstract)
- Psychosocial factors in natural family planning: an overview (Sharma). 1991;165:2077 (Abstract)
- XV. Roundtable discussions (Vogelsang). 1991;165:2075-6 (Abstract)
- Social science natural family planning issues (Sharma et al). 1991;165:2076-7 (Abstract)
- Toward better marriages through natural family planning (Osmund-Ruiz). 1991;165:2076 (Abstract)

Natural family planning, standards

- Automated management information systems (Nesbitt). 1991;165:2074 (Abstract)
- The effect of supervision on program development and quality of services (St. Mart). 1991;165:2074 (Abstract)
- A management needs assessment for African natural family planning programs: process and results (Pedersen). 1991;165:2073 (Abstract)
- Service delivery part 2: elements necessary for success (Jennings et al). 1991;165:2073-4 (Abstract)
- Targeting quality of care: a strategy for successful periodic abstinence services (Kopp). 1991;165:2074 (Abstract)

Natural family planning, trends

- Introduction: principles for meeting increased demand (Jennings and O'Rourke). 1991;165:2073 (Abstract)
- Natural family planning: current knowledge and new strategies for the 1990s—Session I: discussion and recommendations (Queenan and Moghissi). 1991;165:1992

Natural family planning: current knowledge and new strategies for the 1990s—Session II: discussion and recommendations. 1991;165:2012

Natural family planning: looking ahead (Queenan and Moghissi). 1991;165:1979-80

Natural family planning, utilization

Creating a demand for scientific natural family planning: the Zambian experience (Tafira). 1991;165:2070 (Abstract)

Effectiveness and acceptability of the symptothermal method of natural family planning in Germany (Frank-Herrmann et al). 1991;165:2052-4

Efficacy studies in natural family planning: issues and management implications illustrated with data from five studies (Labbok et al). 1991;165:2048-51

Evaluation of natural family planning programs in Liberia and Zambia (Kambic et al). 1991;165:2078 (Abstract)

Factors related to autonomy and discontinuation of use of natural family planning for women in Liberia and Zambia (Kambic and Gray). 1991;165:2060-2

Introduction: principles for meeting increased demand (Jennings and O'Rourke). 1991;165:2073 (Abstract)

Measuring natural family planning in terms of couple-years of protection (Cuervo). 1991;165:2063-5

Natural family planning: current knowledge and new strategies for the 1990s—Session IV: discussion and recommendations. 1991;165:2068

Natural family planning use-effectiveness and continuation (Kambic). 1991;165:2046-8

Natural family planning use in Peru (Sharma). 1991;165:2077 (Abstract)

The 1991 Mauritius contraceptive prevalence study (Chen et al). 1991;165:2077 (Abstract)

Social science natural family planning issues (Sharma et al). 1991;165:2076-7 (Abstract)

Using quantitative data to define natural family planning use: a profile (Sharma). 1991;165:2070 (Abstract)

Natural killer cells; see Killer cells, natural Necrosis

Thrombotic thrombocytopenic purpura first seen as massive vaginal necrosis (Gallup et al). 1991;165:413-5

Neonatal hyperbilirubinemia; see Jaundice, neonatal

Neonate; see Infant, newborn

Neoplasm invasiveness

Primary invasive vaginal carcinoma (Eddy et al). 1991; 165:292-8

Neoplasms

The prevalence of recurrent spontaneous abortions, cancer, and congenital anomalies in the families of couples with recurrent spontaneous abortions or gestational trophoblastic tumors (Ho et al). 1991;165:461-6

Ultrastructural study of glandular epithelium in adenomyosis in comparison with those of proliferative endometrium and well-differentiated endometrial cancer (Hayata). 1991;165:225-8 (Symposium)

Neopterin

Prognostic value of CA 125 and neopterin in women with ovarian cancer undergoing second-look laparotomy (Fuith et al). 1991;165:779 (Letter)

neu proto-oncogene; see Proto-oncogenes

Neural tube defects

Risk of open spina bifida (Hershey) (Letter); (Thornton) (Reply), 1991;165:1159

Risks associated with an elevated maternal serum α-fetoprotein level (Crandall et al). 1991;165:581-6 Value of high and low maternal serum α-fetoprotein levels in screening singleton pregnancies (Minaretzis and Tsionou) (Letter); (Milunsky) (Reply). 1991;165:780

Neuralgia

Pudendal neuralgia (Turner and Marinoff). 1991;165: 1233-6

Neutropenia

The mechanism responsible for diminished neutrophil production in neonates delivered of women with pregnancy-induced hypertension (Koenig and Christensen). 1991;165:467-73

Neutrophils

Amniotic fluid white blood cell count: a rapid and simple test to diagnose microbial invasion of the amniotic cavity and predict preterm delivery (Romero et al). 1991;165:821-30

The mechanism responsible for diminished neutrophil production in neonates delivered of women with pregnancy-induced hypertension (Koenig and Christensen). 1991;165:467-73

Neutrophil attractant/activating peptide-1/interleukin-8 in term and preterm parturition (Romero et al). 1991;165:813-20

New Zealand

Psychosexual aspects of natural family planning as revealed in the World Health Organization multicenter trial of the ovulation method and the New Zealand continuation study (France). 1991;165:2077 (Abstract)

Nifedipine

Nifedipine pharmacokinetics and pharmacodynamics during the immediate postpartum period in patients with preeclampsia (Barton et al). 1991;165:951-4

Nitroimidazoles

Trichomoniasis: trends in diagnosis and management (Lossick and Kent). 1991;165:1217-22

Nonimmune hydrops fetalis; see Hydrops fetalis

Nonstress test; see Fetal monitoring

Norepinephrine

Fetal hypertension induced by norepinephrine infusion and umbilical artery flow velocity waveforms in fetal sheep (van Huisseling et al). 1991;165:450-5

Novak curette

A prospective, randomized comparison of the Pipelle endometrial sampling device with the Novak curette (Stovall et al). 1991;165:1287-9

Ó

Occupational exposures; see Environmental exposure Oligohydramnios

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep (Arnold-Aldea et al). 1991;165:185-90

Oligohydramnios: antepartum fetal urine production and intrapartum fetal distress (Groome et al). 1991;165:1077-80

Prophylactic amnioinfusion as a treatment for oligohydramnios in laboring patients: a prospective, randomized trial (Schrimmer et al). 1991;165:972-5

Transcervical chorionic villus sampling and midtrimester oligohydramnios (Cheng et al). 1991;165:1063-8

Variable decelerations in reactive nonstress tests with decreased amniotic fluid index predict fetal compromise (Hoskins et al). 1991;165:1094-8

Oligospermia

Evidence for a partial deletion in the androgen receptor

1960 Subject index

December 1991

Am | Obstet Gynecol

Oligospermia-cont'd

gene in a phenotypic male with azoospermia (Akin et al). 1991;165:1891-4

Onapristone

The progesterone antagonist onapristone increases the effectiveness of oxytocin to produce delivery without changing the myometrial oxytocin receptor concentrations (Chwalisz et al). 1991;165:1760-70

Oncogenes

C-jun and jun-B oncogene expression during placental development (Dungy et al). 1991;165:1853-6

Oophorectomy; see Ovariectomy

Open spina bifida; see Spina bifida cystica

Operations research

Current status of operations research in natural family planning (Ricci and Seidman). 1991;165:2077 (Abstract)

Operations research in natural family planning: strategies, issues, and research approaches (Ricci et al). 1991;165:2077-8 (Abstract)

Political and practical issues in the implementation of operations research studies in natural family planning (Townsend and Vernon). 1991;165:2078 (Abstract)

Using operations research to improve natural family planning program services, management, and policy (Wawer et al). 1991;165:2078 (Abstract)

Opiates; see Narcotics

Oral contraceptives; see Contraceptives, oral

Oral mucosa, animal; see Mouth mucosa, animal

Organic solvents; see Solvents Organization and administration

The effect of supervision on program development and quality of services (St. Mart). 1991;165:2074 (Abstract)

Ovarian hyperstimulation

Severe ovarian hyperstimulation in a spontaneous singleton pregnancy (Rosen and Lew). 1991;165:1312-3

Ovarian neoplasms

CA 125 regression: a model for epithelial ovarian cancer response (Buller et al). 1991;165:360-7

Characterization of in vitro chemosensitivity of perioperative human ovarian malignancies by adenosine triphosphate chemosensitivity assay (Gerhardt et al). 1991; 165:245-55

Expression and amplification of the HER-2/neu (c-erbB-2) protooncogene in epithelial ovarian tumors and cell lines (Tyson et al). 1991;165:640-6

Hexamethylmelamine chemotherapy for persistent or recurrent epithelial ovarian cancer (Moore et al). 1991;165:573-6

Increased serum levels of macrophage colony-stimulating factor in ovarian cancer (Xu et al). 1991;165:1356-62

Ovarian cancer screening: potential effect on mortality (Westhoff and Randall). 1991;165:502-5

Prognostic value of CA 125 and neopterin in women with ovarian cancer undergoing second-look laparotomy (Fuith et al). 1991;165:779 (Letter)

Prolonged clearance of intraperitoneal 16α-[¹²⁵I]iodo-17β-estradiol in presence of ascites (Scharl et al). 1991;165:1847-53

Screening in ovarian cancer (Creasman and DiSaia). 1991;165:7-10 (Clin. opinion)

Ovariectomy

Transvaginal removal of ovaries with endoloop sutures at the time of transvaginal hysterectomy (Hoffman). 1991;165:407-8 Videolaseroscopy for oophorectomy (Nezhat et al). 1991; 165:1323-30

Ovary, physiology

Ultrasonographic patterns of ovarian activity during breast-feeding (Flynn et al). 1991;165:2027-31

Oviducts

Egg transport through the oviduct (Beer and Folghera). 1991;165:483 (Letter)

Ovulation

The gonadotropin-releasing hormone antagonist (Nal-Glu) acutely blocks the luteinizing hormone surge but allows for resumption of folliculogenesis in normal women (Dit-koff et al). 1991;165:1811-7

Severe ovarian hyperstimulation in a spontaneous singleton pregnancy (Rosen and Lew). 1991;165:1312-3

Ovulation, animal

Effects of intravenous cocaine on reproductive function in the mated rabbit (Atlas and Wallach). 1991;165:1785-90

Ovulation detection

Effectiveness and acceptability of the symptothermal method of natural family planning in Germany (Frank-Herrmann et al). 1991;165:2052-4

Efficacy of the symptothermal method of natural family planning in lactating women after the return of menses (Zinaman and Stevenson). 1991;165:2037-9

Efficacy studies in natural family planning: issues and management implications illustrated with data from five studies (Labbok et al). 1991;165:2048-51

The evolution of reference methods to monitor ovulation: How well do current markers perform? (Collins). 1991:165:1994-6

Further analysis of contraceptive failure of the ovulation method (Trussell and Grummer-Strawn). 1991;165:2054-9

Home tests to monitor fertility (May). 1991;165:2000-2

Natural family planning: looking ahead (Queenan and Moghissi). 1991;165:1979-80

Overview and issues in ovulation prediction (Zinaman and France). 1991;165:1993

Ovulation method use during breastfeeding: Is there increased risk of unplanned pregnancy? (Labbok et al). 1991;165:2031-6

A profile of successful versus unsuccessful ovulation method users: factors associated with unplanned pregnancy and nonadherence to the rules (Labbok et al). 1991;165:2077 (Abstract)

A prototype for ovulation detection: pros and cons (Lasley et al). 1991;165:2003-7

Psychosexual aspects of natural family planning as revealed in the World Health Organization multicenter trial of the ovulation method and the New Zealand continuation study (France). 1991;165:2077 (Abstract)

Symptothermal and hormonal markers of potential fertility in climacteric women (Flynn et al). 1991;165: 1987-9

Ovum implantation

Partial dissection of the zona pellucida of frozen-thawed human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Ovum implantation, animal

Daily administration of the progesterone antagonist RU 486 prevents implantation in the cycling guinea pig (Batista et al). 1991;165:82-6

Ovum transport

Egg transport through the oviduct (Beer and Folghera). 1991;165:483 (Letter)

Oxytocin

- Case report of myocardial infarction in labor (Menegakis and Amstey). 1991;165:1383-4
- The effect of amnioinfusion on uterine pressure and activity (Miyazaki) (Letter); (Posner) (Reply). 1991;165:1898-9
- Fetal breathing movements before oxytocin induction in prolonged pregnancies (Schreyer et al). 1991;165:577-81
- Inhibition of oxytocin-induced uterine contractions by an oxytocin antagonist in the pregnant baboon (Wilson et al). 1991;165:456-60
- Oxytocin secretion and human parturition: pulse frequency and duration increase during spontaneous labor in women (Fuchs et al). 1991;165:1515-23
- The progesterone antagonist onapristone increases the effectiveness of oxytocin to produce delivery without changing the myometrial oxytocin receptor concentrations (Chwalisz et al). 1991;165:1760-70
- A prospective study of two dosing regimens of oxytocin for the induction of labor in patients with unfavorable cervices (Satin et al). 1991;165:980-4

F

Pain

- Correlation between sexual abuse and somatization inwomen with somatic and nonsomatic chronic pelvic pain (Reiter et al). 1991;165:104-9
- Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al): 1991;165:745-9 (Curr. dev.)

Pancuronium

Risk factors for cordocentesis and fetal intravascular transfusion (Weiner et al). 1991;165:1020-5

Papanicolaou smear; see Vaginal smears.

Papers

Papers of the Society for Gynecologic Investigation. 1991;165:1639-938

Papillomaviruses

- Expression of cytokine receptors and markers of differentiation in human papillomavirus—infected cervical tissues (McGlennen et al). 1991;165:696-705
- High risk of human papillomavirus infection and cervical squamous intraepithelial lesions among women with symptomatic human immunodeficiency virus infection (Vermund et al). 1991;165:392-400
- Human papillomavirus infection in women with multicentric squamous cell neoplasia (Beckmann et al). 1991;165:1431-7
- Vaginal cancer: the role of infectious and environmental factors (Merino). 1991;165:1255-62
- Vulvar squamous cell carcinoma and papillomaviruses: Two separate entities? (Andersen et al). 1991;165:329-36
- Vulvar vestibulitis syndrome: an overview (Marinoff and Turner). 1991;165:1228-33
- Vulvovaginal human papillomavirus infections: clinical implications and management (Hatch). 1991;165: 1183-8

Paraventricular hypothalamic nucleus, animal-

Bilateral destruction of the fetal paraventricular nuclei prolongs gestation in sheep (McDonald and Nathanielsz). 1991;165:764-70

Parturition; see Labor

Pathology

Examination of placentas by pathologists (Goldman) (Letter); (Salafia and Vintzileos) (Reply). 1991;165:783-4

Patient compliance

Vulvovaginitis: the role of patient compliance in treatment success (Nixon). 1991;165:1207-9

Patient education

- Adapting data systems of multimethod programs to incorporate natural family planning (Cuervo). 1991;165:2074 (Abstract)
- An American national experience: natural family planning serves under the auspices of the Roman Catholic Church (Notare). 1991;165:2073 (Abstract)
- Assessment of Kegel pelvic muscle exercise performance after brief verbal instruction (Bump et al). 1991;165:322-9
- Center for Research, Education, Service and Training's fertility education program for youth (Mascarenhas). 1991;165:2070 (Abstract)
- Client teaching materials for francophone Africa (Ecochard). 1991;165:2072 (Abstract)
- Creating a demand for scientific natural family planning: the Zambian experience (Tafira). 1991;165:2070 (Abstract)
- Current natural family planning programs and strategies for expanding service delivery: an introduction (Mejia and Solis). 1991;165:2072 (Abstract)
- Expanding natural family planning through vocational schools for women in Cote d'Ivoire (Rodriguez-Garcia). 1991;165:2073 (Abstract)
- Experiences and trends in natural family planning education and outreach (Rodriguez-Garcia et al). 1991;165:2070-1 (Abstract)
- Experiences in the field: Confederação Nacional de Centros de Planejamento Natural da Familia, Brazil (Sogayar). 1991;165:2071 (Abstract)
- Fertility education for young men (Burke). 1991;165:2071 (Abstract)
- Innovative approaches from population communication services: implications for natural family planning (Lozaré). 1991;165:2070 (Abstract)
- Introduction of natural family planning information into multimethod materials for trainers (Lea and Murphy). 1991;165:2071 (Abstract)
- Issues in the development and dissemination of training and educational materials (Schaefer). 1991;165:2071 (Abstract)
- Lessons learned from a mass-media campaign in Peru (Tagliabue). 1991;165:2070 (Abstract)
- Materials development, testing, and evaluation: an overview (Zimmerman and Bartlett). 1991;165:2071 (Abstract)
- Materials development in Zambia: concept versus reality (Tafira). 1991;165:2071 (Abstract)
- Materials for the modified mucus method (Dorairaj). 1991;165:2072 (Abstract)
- Materials in the United States: an example from Los Angeles (Minervini). 1991;165:2072 (Abstract)
- Materials translation: Is that really what you want to say? (Bowen and Bowen). 1991;165:2071 (Abstract)
- The missing link—why natural family planning is still "the best kept secret" (Ek). 1991;165:2075 (Abstract)
- Natural family planning: national program development in Kenya (Wahome and Mwaulu). 1991;165:2073 (Abstract) Natural family planning in a family planning program

(Kring). 1991;165:2072 (Abstract)

Patient education-cont'd

- Natural family planning through the health sector in India (Mascarenhas). 1991;165:2073 (Abstract)
- New approaches to expanding natural family planning (Skipp). 1991;165:2072 (Abstract)
- New directions for education and outreach in the 1990s (Rodriguez-Garcia). 1991;165:2070 (Abstract)
- A pilot study on teaching natural family planning in general practice (Clubb et al). 1991;165:2078 (Abstract)
- A pilot study on teaching natural family planning in general practice (Pyper). 1991;165:2076 (Abstract)
- Providing natural family planning counseling within a family planning clinic (Minervini). 1991;165:2076 (Abstract)
- Reaching new populations with natural family planning education (Mehra). 1991;165:2070 (Abstract)
- XV. Roundtable discussions (Vogelsang). 1991;165:2075-6 (Abstract)
- Seeking opportunities for natural family planning expansion: the Serena experience (Parenteau-Carreau). 1991;165:2070 (Abstract)
- Service delivery part 1: current programs and strategies for expansion (Mejia et al). 1991;165:2072-3 (Abstract)
- Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cohort (Klaus and Kardatzke). 1991;165:2071 (Abstract)
- Training and educational materials (Schaefer et al). 1991;165:2071-2 (Abstract)

Pelvic pain; see Pain

Pelvicalyceal dilation; see Hydronephrosis Pelvimetry

The fetal-pelvic index: a method of identifying fetal-pelvic disproportion in women attempting vaginal birth after previous cesarean delivery (Thurnau et al). 1991;165: 353-8

Pelvis

- Arterial blood flow velocity waveforms of the pelvis and lower extremities in normal and growth-retarded fetuses (Mari). 1991;165:143-51
- Assessment of Kegel pelvic muscle exercise performance after brief verbal instruction (Bump et al). 1991;165:322-9
- Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al). 1991;165:745-9 (Curr. dev.)
- Resolution of chronic pelvic pain after laparoscopic lysis of adhesions (Steege and Stout). 1991;165:278-83

Pelvis, surgery, animal

The ability of recombinant tissue plasminogen activator to inhibit post—radical pelvic surgery adhesions in the dog model (Montz et al). 1991;165:1539-42

Peritoneal cavity

Effects of peritoneal macrophages from patients with endometriosis on the proliferation of endometrial carcinoma cell line ECC-1 (Zhang et al). 1991;165: 1842-6

Peritoneoscopy

- Case report of laparoscopic cholecystectomy in the third trimester of pregnancy (Pucci and Seed). 1991;165:401-2
- Incidental appendectomy during videolaseroscopy (Nezhat and Nezhat). 1991;165:559-64
- Laparoscopic ventrosuspensions (Cristalli) (Letter); (Yoong) (Reply). 1991;165:780-1

- Pelvic denervation for chronic pain associated with endometriosis: Fact or fancy? (Vercellini et al). 1991;165:745-9 (Curr. dev.)
- Resolution of chronic pelvic pain after laparoscopic lysis of adhesions (Steege and Stout). 1991;165:278-83
- Videolaseroscopy for oophorectomy (Nezhat et al). 1991;165:1323-30

Peru

- Lessons learned from a mass-media campaign in Peru (Tagliabue). 1991;165:2070 (Abstract)
- Natural family planning use in Peru (Sharma). 1991;165:2077 (Abstract)

Phenytoin

Magnesium sulfate versus phenytoin for seizure prophylaxis in pregnancy-induced hypertension (Appleton et al). 1991;165:907-13

Philippines

Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cohort (Klaus and Kardatzke). 1991;165:2071 (Abstract)

Phospholipids

- Lack of an association between late fetal death and antiphospholipid antibody measurements in the second trimester (Haddow et al). 1991;165:1308-12
- Should anticardiolipin tests be performed in otherwise healthy pregnant women? (Harris and Spinnato). 1991;165:1272-7

Pipelle endometrial sampling device

A prospective, randomized comparison of the Pipelle endometrial sampling device with the Novak curette (Stovall et al). 1991;165:1287-9

Placenta

- C-jun and jun-B oncogene expression during placental development (Dungy et al). 1991;165:1853-6
- Costs and benefits of examining all placentas (Mittal) (Letter); (Salafia and Vintzileos) (Reply). 1991;165:235
- Cytologic localization of epidermal growth factor and its receptor in developing human placenta varies over the course of pregnancy (Ladines-Llave et al). 1991;165: 1377-82
- Dose-related action of gonadotropin-releasing hormone on basal prostanoid production from the human term placenta (Kang et al). 1991;165:1771-6
- Effects of leukotrienes in the placental vasculature (Sullivan et al) (Letter); (Walsh) (Reply). 1991;165:1575-6
- Effects of maternally administered epidermal growth factor on placental permeability (Mimouni et al). 1991;165:173-6
- Endothelin-1—induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation (Myatt et al). 1991;165:1717-22
- The enhanced production of placental interleukin-1 during labor and intrauterine infection (Taniguchi et al). 1991;165:131-7
- Examination of placentas by pathologists (Goldman) (Letter); (Salafia and Vintzileos) (Reply). 1991;165: 783-4
- Inhibin subunits in human placenta: localization and messenger ribonucleic acid levels during pregnancy (Petraglia et al). 1991;165:750-8
- Insignificant transfer of glyburide occurs across the human placenta (Elliott et al). 1991;165:807-12
- Placental pathologic findings in preterm birth (Salafia et al). 1991;165:934-8. 1991;165:1903 (Correction)

Report of fourteen cases of nonimmune hydrops fetalis in association with hemorrhagic endovasculitis of the placenta (Novak et al). 1991;165:945-50

Transforming growth factor-β₁ expression during placental development (Dungy et al). 1991;165:853-7

Twin gestation: influence of placentation on fetal growth (Pridjian et al). 1991;165:1394-401

Placenta diseases

Association of immunoreactive eosinophil major basic protein with placental septa and cysts (Wasmoen et al). 1991;165:416-20

Placenta previa

Cigarette smoking during pregnancy in relation to placenta previa (Williams et al). 1991;165:28-32

What is a low-lying placenta? (Oppenheimer et al). 1991;165:1036-8

Placental membranes; see Fetal membranes

Placental proteins; see Pregnancy proteins

Plasma volume, animal

Atrial natriuretic factor responses to volume expansion in pregnant and nonpregnant sheep (Bennett and Rose). 1991;165:1627-34

Plasminogen activator, tissue-type

The ability of recombinant tissue plasminogen activator to inhibit post—radical pelvic surgery adhesions in the dog model (Montz et al). 1991;165:1539-42

Platelet activating factor

Anticardiolipin antibody-positive serum enhances endothelial cell platelet-activating factor production (Silver et al). 1991;165:1748-52

Platelet aggregation

The effect of the menstrual cycle and of decompression stress on arachidonic acid-induced platelet aggregation and on intrinsic platelet thromboxane production in women compared with men (Markham et al). 1991; 165:1821-9

Plethysmography, impedance

Effect of pregnancy on the accuracy of light-reflection rheography (Allbert et al). 1991;165:1745-7

Policy making

Communicating with developing country policymakers: the case for natural family planning (Murphy). 1991;165: 2075 (Abstract)

Gaining policy support for natural family planning (Jennings). 1991;165:2074 (Abstract)

International Planned Parenthood Federation's policy and support for periodic abstinence: rationale and future plans (Kopp). 1991;165:2075 (Abstract)

Natural family planning: Agency for International Development policy considerations (Clark and Spieler). 1991;165:2074 (Abstract)

Policies and support for natural family planning: rationales and future plans (Donayre). 1991;165:2075 (Abstract)

Policy issues in natural family planning (Jennings et al). 1991;165:2074-5 (Abstract)

From policy to norms to services: developing a consensus for natural family planning (Skipp). 1991;165:2075 (Abstract)

Understanding policy and the policy-making process: considerations for initiating policy interest (Rodriguez-Garcia). 1991;165:2075 (Abstract)

World Health Organization's policy considerations in natural family planning (Mehra). 1991;165:2075 (Abstract)

Polyamines

Failure to verify high activities of polyamine oxidase in pregnancy serum (Kumazawa et al). 1991;165:1457-8

Polycystic ovary syndrome

Adrenal and ovarian steroid hormone responses to gonadotropin-releasing hormone agonist treatment in polycystic ovary syndrome (Gonzalez et al). 1991;165:535-45

Polycystic ovary syndrome and the androgen-insulin connection (Nader). 1991;165:346-8 (Clin. opinion)

Polyhydramnios

Study of 156 cases of polyhydramnios and congenital malformations in a series of 118,265 consecutive births (Stoll et al). 1991;165:586-90

Polyhydramnios, animal

Amnioinfusion increases amniotic pressure in pregnant sheep but does not alter fetal acid-base status (Fisk et al). 1991;165:1459-63

Amniotic fluid volume response to esophageal occlusion in fetal sheep (Fujino et al). 1991;165:1620-6

Elevated fetal plasma lactate produces polyhydramnios in the sheep (Powell and Brace). 1991;165:1595-607

Polymerase chain reaction

Human papillomavirus infection in women with multicentric squamous cell neoplasia (Beckmann et al). 1991;165:1431-7

In utero diagnosis of congenital varicella zoster virus infection by chorionic villus sampling and polymerase chain reaction (Isada et al). 1991;165:1727-30

Postmenopause; see Menopause

Postoperative complications

Extensive pulmonary embolism presenting as severe adult respiratory distress syndrome after surgical resection of a cornual pregnancy (tenHoopen et al). 1991;165: 41-2

Postpartum hemorrhage

Obstetric complications in a patient with Bernard-Soulier syndrome (Peng et al). 1991;165:425-6

Vasopressin and operative hysteroscopy in the management of delayed postabortion and postpartum bleeding (Townsend et al). 1991;165:616-8

Postpartum period; see Puerperium

Posture

Regulation of atrial natriuretic peptide release in pregnancy: responses to posture (Lowe et al). 1991;165:591-5

Potassium

Effects of magnesium and terbutaline on contractility and K⁺ uptake in isolated human uterine muscle (Skajaa et al). 1991;165:1543-51

Pre-eclampsia

A case report of massive vulvar edema during tocolysis of preterm labor (Brittain et al). 1991;165:420-2

Concentration of digoxin-like immunoreactive substance in patients with preeclampsia and its relation to severity of pregnancy-induced hypertension (Kaminski and Rechberger). 1991;165:733-6

Early detection of preeclampsia (Dekker and Sibai). 1991;165:160-72 (Curr. dev.)

Endomyocardial ultrastructural findings in preeclampsia (Barton et al). 1991;165:389-91

Epidemiology of preeclampsia and eclampsia (Ales and Charlson) (Letter); (Saftlas et al) (Reply). 1991;165:238

Fibrinolytic parameters in normotensive pregnancy with intrauterine fetal growth retardation and in severe pre-eclampsia (Estellés et al). 1991;165:138-42

Pre-eclampsia--cont'd

- Hemostatic wrapping of ruptured liver in two postpartum patients (Rittenberry et al). 1991;165:705-7
- High blood pressure in pregnancy (Iffy and Ganesh). 1991;165:236-7 (Letter)
- High plasma cellular fibronectin levels correlate with biochemical and clinical features of preeclampsia but cannot be attributed to hypertension alone (Taylor et al). 1991:165:895-901
- The imbalance between thromboxane and prostacyclin in preeclampsia is associated with an imbalance between lipid peroxides and vitamin E in maternal blood (Wang et al). 1991;165:1695-700
- Indomethacin induces hypertensive crisis in preeclampsia irrespective of prior antihypertensive drug therapy (Mousavy) (Letter); (Schoenfeld) (Reply). 1991;165:1577
- Maternal plasma level of endothelin is increased in preeclampsia (Nova et al). 1991;165:724-7
- Nifedipine pharmacokinetics and pharmacodynamics during the immediate postpartum period in patients with preeclampsia (Barton et al). 1991;165:951-4
- Patients with preeclampsia may be insensitive to atrial natriuretic factor (Goodlin). 1991;165:1161 (Letter)
- Postpartum preeclampsia-induced shock and death: a report of three cases (Kalur et al). 1991;165:1362-8
- Potential role of endothelin-1 in normal and hypertensive pregnancies (Mastrogiannis et al). 1991;165:1711-6
- Relationship between central venous pressure and pulmonary capillary wedge pressure in severely toxemic patients (Tellez). 1991;165:487 (Letter)
- Selective effects of preeclamptic sera on human endothelial cell procoagulant protein expression (Taylor et al). 1991;165:1705-10
- Severe preeclampsia in the second trimester: recurrence risk and long-term prognosis (Sibai et al). 1991;165: 1408-12
- Transfer of aspirin across the perfused human placental cotyledon (Jacobson et al). 1991;165:939-44

Predictive value of tests

- Early detection of preeclampsia (Dekker and Sibai). 1991;165:160-72 (Curr. dev.)
- Predictive value of early embryonic cardiac activity for pregnancy outcome (Merchiers et al). 1991;165:11-4

Prednisone

Loxoscelism threatening pregnancy: five cases (Anderson). 1991;165:1454-6

Pregnancy, animal

- Amnioinfusion increases amniotic pressure in pregnant sheep but does not alter fetal acid-base status (Fisk et al). 1991;165:1459-63
- Circadian rhythms of heart rate and mean arterial pressure in chronically instrumented pregnant rats (Melone et al). 1991;165:758-63
- The effect of hypothalamic lesions on the length of gestation in fetal sheep (Gluckman et al). 1991;165:1464-8
- Effects of intravenous cocaine on reproductive function in the mated rabbit (Atlas and Wallach). 1991;165:1785-90
- Forward shift in the initiation of the nocturnal estradiol surge in the pregnant baboon: Is this the genesis of labor? (Wilson et al). 1991;165:1487-98
- Postbinding insulin resistance around parturition in the isolated rat epitrochlearis muscle (Toyoda et al). 1991;165:1475-80

Pregnancy, blood

Fibrinolytic parameters in normotensive pregnancy with in-

trauterine fetal growth retardation and in severe preeclampsia (Estellés et al). 1991;165:138-42

Pregnancy, drug effects

- Cigarette smoking during pregnancy in relation to placenta previa (Williams et al). 1991;165:28-32
- Effect of cigarette smoking on maternal airway function during pregnancy (Das et al). 1991;165:675-9
- The effect of maternal cocaine use on the fetus: changes in antepartum fetal heart rate tracings (Tabor et al). 1991;165:1278-81
- Effects of angiotensin II on atrial natriuretic peptide in pregnancy (Didden et al). 1991;165:692-5
- Identifying pregnant women who drink alcoholic beverages (Mullen et al). 1991;165:1429-30
- Improving disclosure of smoking by pregnant women (Mullen et al). 1991;165:409-13
- Insignificant transfer of glyburide occurs across the human placenta (Elliott et al). 1991;165:807-12
- Magnesium sulfate versus phenytoin for seizure prophylaxis in pregnancy-induced hypertension (Appleton et al). 1991;165:907-13
- Medication in early pregnancy: prevalence of use and relationship to maternal characteristics (Buitendijk and Bracken). 1991;165:33-40
- Sister chromatid exchange frequency in directly prepared cytotrophoblasts: demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes (Shulman et al). 1991;165:1877-80
- Thrombotic thrombocytopenic purpura first seen as massive vaginal necrosis (Gallup et al). 1991;165:413-5

Pregnancy, ectopic

- Alternative estimates of ectopic pregnancy risks during contraception (Sivin) (Letter); (Franks and Beral) (Reply). 1991;165:1899-900
- Extensive pulmonary embolism presenting as severe adult respiratory distress syndrome after surgical resection of a cornual pregnancy (tenHoopen et al). 1991;165:
- Recurrence of ectopic pregnancy: the role of salpingitis (Joesoef et al). 1991;165:46-50
- Ultrasonographic visualization of endometrial vascularity with ectopic pregnancy (Cadkin and Applebaum). 1991;165:236 (Letter)

Pregnancy, genetics

The effect of trisomy 18 on transverse cerebellar diameter (Hill et al). 1991;165:72-5

Pregnancy, immunology

Natural killer cell cytotoxicity to herpes simplex virus-1—infected cells is not altered by pregnancy (Eriksen et al). 1991;165:965-8

Pregnancy, mortality

The pathology of maternal mortality (Shanklin et al). 1991;165:1126-55

Pregnancy, multiple

- Multifetal pregnancy reduction and disposal of untransplanted embryos in contemporary Jewish law and ethics (Grazi and Wolowelsky). 1991;165:1268-71 (Clin. opinion)
- The origin of brain lesions in survivors of twin gestations complicated by fetal death (Gonen). 1991;165:1897-8 (Letter)
- Twin gestation: influence of placentation on fetal growth (Pridjian et al). 1991;165:1394-401

Pregnancy, physiology

Antioxidant systems in normal pregnancy and in preg-

- nancy-induced hypertension (Wisdom et al). 1991;165:1701-4
- Baroreflex function in normal pregnancy (Leduc et al). 1991;165:886-90
- The changing glycemic response to exercise during pregnancy (Clapp and Capeless). 1991;165:1678-83
- The changing thermal response to endurance exercise during pregnancy (Clapp). 1991;165:1684-9
- Does the brachial artery Doppler flow velocity waveform reflect changes in downstream impedance? (Fairlie and Walker). 1991;165:1741-4
- Dose-related action of gonadotropin-releasing hormone on basal prostanoid production from the human term placenta (Kang et al). 1991;165:1771-6
- Effect of pregnancy on the accuracy of light-reflection rheography (Allbert et al). 1991;165:1745-7
- An endothelial cell model for the investigation of the molecular regulation of fetal vascular tone (Dudley et al). 1991;165:1723-6
- Endothelin-1—induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation (Myatt et al). 1991;165:1717-22
- Longitudinal changes in insulin release and insulin resistance in nonobese pregnant women (Catalano et al). 1991;165:1667-72
- Maternal levels of prostacyclin, thromboxane, vitamin E, and lipid peroxides throughout normal pregnancy (Wang et al). 1991;165:1690-4
- Potential role of endothelin-1 in normal and hypertensive pregnancies (Mastrogiannis et al). 1991;165:1711-6

Pregnancy, prolonged

Fetal breathing movements before oxytocin induction in prolonged pregnancies (Schreyer et al). 1991;165:577-

Pregnancy, psychology

- Psychosocial support for maternal stress during pregnancy: effect on birth weight (Rothberg and Lits). 1991;165:403-7
- Recurrent mild abruptio placentae occurring immediately after repeated electroconvulsive therapy in pregnancy (Sherer et al). 1991;165:652-3

Pregnancy complications

- Case report of laparoscopic cholecystectomy in the third trimester of pregnancy (Pucci and Seed). 1991;165:401-2
- Loxoscelism threatening pregnancy: five cases (Anderson). 1991:165:1454-6
- Pemphigus gestationis (herpes gestationis): a case report (Wolman et al). 1991;165:743-4
- Pregnancy and Wilson's disease (Chin) (Letter); (Dupont et al) (Reply). 1991;165:488-9
- Trophoblast from anembryonic pregnancy has both a maternal and a paternal contribution to its genome (Henderson et al). 1991;165:98-102
- Untreated luteal phase deficiency as another possible risk factor for preterm delivery (Check and Lee) (Letter); (McGregor and French) (Reply). 1991;165:485-6

Pregnancy complications, cardiovascular; see also Hypertension; Pre-eclampsia

- Case report of myocardial infarction in labor (Menegakis and Amstey). 1991;165:1383-4
- Concentration of digoxin-like immunoreactive substance in patients with preeclampsia and its relation to severity of pregnancy-induced hypertension (Kaminski and Rechberger). 1991;165:733-6

- The effect of maternal hemodynamics on fetal growth in hypertensive pregnancies (Easterling et al). 1991;165: 902-6
- High blood pressure in pregnancy (Iffy and Ganesh). 1991;165:236-7 (Letter)
- High plasma cellular fibronectin levels correlate with biochemical and clinical features of preeclampsia but cannot be attributed to hypertension alone (Taylor et al). 1991;165:895-901
- Magnesium sulfate versus phenytoin for seizure prophylaxis in pregnancy-induced hypertension (Appleton et al). 1991;165:907-13
- The mechanism responsible for diminished neutrophil production in neonates delivered of women with pregnancy-induced hypertension (Koenig and Christensen). 1991; 165:467-73
- Nifedipine pharmacokinetics and pharmacodynamics during the immediate postpartum period in patients with preeclampsia (Barton et al). 1991;165:951-4
- Patients with preeclampsia may be insensitive to atrial natriuretic factor (Goodlin). 1991;165:1161 (Letter)
- The prevalence of autoantibodies during third-trimester pregnancy complicated by hypertension or idiopathic fetal growth retardation (Milliez et al). 1991;165:51-6
- Transfer of aspirin across the perfused human placental cotyledon (Jacobson et al). 1991;165:939-44

Pregnancy complications, cardiovascular, animal

Enhanced endothelium-derived relaxing factor activity in pregnant, spontaneously hypertensive rats (Ahokas et al). 1991;165:801-7

Pregnancy complications, hematologic

- Administration of heparin by subcutaneous infusion with a programmable pump (Floyd et al). 1991;165:931-3
- Antepartum fetal surveillance tests during sickle cell crisis (Anyaegbunam et al). 1991;165:1081-3
- Enhanced sensitization after cordocentesis in a rhesusisoimmunized pregnancy (MacGregor et al). 1991;155: 382-3
- Obstetric complications in a patient with Bernard-Soulier syndrome (Peng et al). 1991;165:425-6
- Thrombotic thrombocytopenic purpura first seen as massive vaginal necrosis (Gallup et al). 1991;165:413-5
- Ultrasonographic diagnosis of symptomatic deep venous thrombosis in pregnancy (Polak and Wilkinson). 1991; 165:695-9
- Use of hydroxyurea in chronic myeloid leukemia during pregnancy: a case report (Patel et al). 1991;165:565-6

Pregnancy complications, infectious

- Correlation of amniotic fluid glucose concentration and intraamniotic infection in patients with preterm labor or premature rupture of membranes (Gauthier et al). 1991;165:1105-10
- The enhanced production of placental interleukin-1 during labor and intrauterine infection (Taniguchi et al). 1991;165:131-7
- Ethics in medical studies with human subjects (Sherer and Abramowicz) (Letter); (Goldstein and Zimmer) (Reply). 1991;165:1895-6
- Human T-cell lymphotropic virus type I infection and pregnancy: a case-control study and 12-month follow-up of 135 women and their infants (Ville et al). 1991;165:1438-43
- In utero diagnosis of congenital varicella zoster virus infection by chorionic villus sampling and polymerase chain reaction (Isada et al). 1991;165:1727-30

1966 Subject index

December 1991

Am | Obstet Gynecol

Pregnancy complications, infectious—cont'd

- Maternal genital herpes and gender of offspring (Brown and Corey) (Letter); (McGregor) (Reply). 1991;165:784-5
- Microbiologic causes and neonatal outcomes associated with chorioamnion infection (Hillier et al). 1991;165:955-61
- Prenatal diagnosis of fetal cytomegalovirus infection (Lynch et al). 1991;165:714-8
- Preterm premature rupture of membranes: detection of infection (Roussis et al). 1991;165:1099-104
- Renal pelvicalyceal dilation in antepartum pyelonephritis: ultrasonographic findings (Twickler et al). 1991;165: 1115-9

Pregnancy complications, neoplastic

Genetic identification of pregnancies responsible for choriocarcinomas after multiple pregnancies by restriction fragment length polymorphism analysis (Osada et al). 1991;165:682-8

Pregnancy in diabetes

- Does intensive glycemic control in diabetic pregnancies result in normalization of other metabolic fuels? (Reece et al). 1991;165:126-30
- Incidence and risk factors associated with abnormal postpartum glucose tolerance in women with gestational diabetes (Catalano et al). 1991;165:914-9
- The role of repeat glucose tolerance tests in the diagnosis of gestational diabetes (Neiger and Coustan). 1991;165:787-90
- Screening recommendations for gestational diabetes mellitus (Cousins et al). 1991;165:493-6 (Clin. opinion)
- Shoulder dystocia: Should the fetus weighing ≥4000 grams be delivered by cesarean section? (Langer et al). 1991;165:831-7
- Shoulder dystocia and birth trauma in gestational diabetes: a five-year experience (Keller et al). 1991;165:928-30
- Urinary protein/creatinine ratio before and during pregnancy in women with diabetes mellitus (Combs et al). 1991;165:920-3

Pregnancy in diabetes, animal

- Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis (Finley and Norton). 1991;165:1661-6
- The metabolic clearance rate of epinephrine in the fetus of the diabetic ewe (Dickinson et al). 1991;165:1655-60
- Streptozocin-induced diabetes mellitus in the pregnant ewe (Dickinson et al). 1991;165:1673-7

Pregnancy-induced hypertension; see Hypertension Pregnancy maintenance

- Acute cutaneous vasculitis associated with prolonged intravenous ritodrine hydrochloride therapy (Bosnyak et al). 1991;165:427-8
- Antimicrobial therapy in preterm premature rupture of membranes: results of a prospective, double-blind, placebo-controlled trial of erythromycin (McGregor et al). 1991;165:632-40
- Combination antibiotics and indomethacin in idiopathic preterm labor: a randomized double-blind clinical trial (Newton et al). 1991;165:1753-9
- Effects of maternally administered epidermal growth factor on placental permeability (Mimouni et al). 1991;165:173-6
- Home monitoring of uterine contractility (Rhoads et al). 1991;165:2-6 (Clin. opinion)

- Multicenter randomized clinical trial of home uterine activity monitoring for detection of preterm labor (Mou et al). 1991;165:858-66
- Oral tocolysis with magnesium chloride: a randomized controlled prospective clinical trial (Ricci et al). 1991;165:603-10
- The prevalence of recurrent spontaneous abortions, cancer, and congenital anomalies in the families of couples with recurrent spontaneous abortions or gestational trophoblastic tumors (Ho et al). 1991;165:461-6

Pregnancy maintenance, animal

Bilateral destruction of the fetal paraventricular nuclei prolongs gestation in sheep (McDonald and Nathanielsz). 1991;165:764-70

Pregnancy outcome

- Congenital hydronephrosis: correlation of fetal ultrasonographic findings with infant outcome (Corteville et al). 1991;165:384-8
- Fetal outcome among pregnancies in natural family planning acceptors: an international cohort study (Simpson et al). 1991;165:1981-2
- The influence of contamination of culture medium with hepatitis B virus on the outcome of in vitro fertilization pregnancies (van Os et al). 1991;165:152-9
- Maternal perception of decreased fetal movement as an indication for antepartum testing in a low-risk population (Whitty et al). 1991;165:1084-8
- Natural family planning: looking ahead (Queenan and Moghissi). 1991;165:1979-80
- Postnatal outcome depends on prenatal history (Giorlandino) (Letter); (Lipper) (Reply). 1991;165:1159-60
- Predictive value of early embryonic cardiac activity for pregnancy outcome (Merchiers et al). 1991;165:11-4
- Pregnancy and Wilson's disease (Chin) (Letter); (Dupont et al) (Reply). 1991;165:488-9
- Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14
- Should anticardiolipin tests be performed in otherwise healthy pregnant women? (Harris and Spinnato). 1991;165:1272-7

Pregnancy proteins

- Association of immunoreactive eosinophil major basic protein with placental septa and cysts (Wasmoen et al). 1991;165:416-20
- Inhibin subunits in human placenta: localization and messenger ribonucleic acid levels during pregnancy (Petraglia et al). 1991;165:750-8

Pregnancy toxemias

Relationship between central venous pressure and pulmonary capillary wedge pressure in severely toxemic patients (Tellez). 1991;165:487 (Letter)

Pregnancy trimester, first

- Medication in early pregnancy: prevalence of use and relationship to maternal characteristics (Buitendijk and Bracken). 1991;165:33-40
- Transvaginal fetal echocardiography in early pregnancy: normative data (Dolkart and Reimers). 1991;165:688-91

Pregnancy trimester, second

- Are choroid plexus cysts an indication for second-trimester amniocentesis? (Achiron and Mashiach) (Letter); (Benacerraf) (Reply). 1991;165:239-41
- Lack of an association between late fetal death and antiphospholipid antibody measurements in the second trimester (Haddow et al). 1991;165:1308-12

Severe preeclampsia in the second trimester: recurrence risk and long-term prognosis (Sibai et al). 1991;165:1408-12

Transcervical endoscopic verification of congenital anomalies in the second trimester of pregnancy (Cullen et al). 1991;165:95-7

Pregnancy trimester, third

Case report of laparoscopic cholecystectomy in the third trimester of pregnancy (Pucci and Seed). 1991;165:401-2

Fetal heart rate response to vibroacoustic stimulation during low and high heart rate variability episodes in late pregnancy (Spencer et al). 1991;165:86-90

Isolation and purification of microvascular endothelium from human decidual tissue in the late phase of pregnancy (Gallery et al). 1991;165:191-6

The prevalence of autoantibodies during third-trimester pregnancy complicated by hypertension or idiopathic fetal growth retardation (Milliez et al). 1991;165:51-6

Regulation of atrial natriuretic peptide release in pregnancy: responses to posture (Lowe et al). 1991;165:591-5

Premature labor; see Labor, premature

Premature rupture of membranes; see Fetal membranes, premature rupture

Premenstrual syndrome

Tryptophan and neutral amino acids in premenstrual syndrome (Rapkin et al). 1991;165:1830-3

Prenatal care

Comparative efficacy of clindamycin versus erythromycin in eradication of antenatal *Chlamydia trachomatis* (Alger and Lovchik). 1991;165:375-81

Evaluation of obstetric ultrasonography at the first prenatal visit (Barrett and Brinson). 1991;165:1002-5

Prenatal diagnosis; see also Ultrasonography, prenatal

Doppler flow velocities in single umbilical arteries (Duerbeck et al). 1991;165:1120-2

The effect of gestational age on the detection rate of Down's syndrome by maternal serum α-fetoprotein screening (Greenberg et al). 1991;165:1391-3

Hypoplastic left heart syndrome: prenatal diagnosis, clinical profile, and management (Blake et al). 1991;165:529-34

In utero diagnosis of congenital varicella zoster virus infection by chorionic villus sampling and polymerase chain reaction (Isada et al). 1991;165:1727-30

In utero fetal muscle biopsy for the diagnosis of Duchenne muscular dystrophy (Evans et al). 1991;165:728-32

Impact of prenatal testing on maternal-fetal bonding: chorionic villus sampling versus amniocentesis (Caccia et al). 1991;165:1122-5

Prenatal diagnosis of fetal cytomegalovirus infection (Lynch et al). 1991;165:714-8

Prenatal diagnosis with fetal cells isolated from maternal blood by multiparameter flow cytometry (Price et al). 1991;165:1731-7

Prenatal prediction of Down syndrome (Reynolds and Penney) (Letter); (O'Brien) (Reply). 1991;165:781-2

Single-center comparison of results of 1000 prenatal diagnoses with chorionic villus sampling and 1000 diagnoses with amniocentesis (Young et al). 1991;165:255-63

Study of 156 cases of polyhydramnios and congenital malformations in a series of 118,265 consecutive births (Stoll et al). 1991;165:586-90

Transcervical chorionic villus sampling and midtrimester oligohydramnios (Cheng et al). 1991;165:1063-8

Prenatal risk assessment; see Risk factors

Presentation at delivery; see Labor presentationPreterm labor; see Labor, premature

Professional competence

Our shield: competence with compassion (Laffitte). 1991;165:243-4 (Pres. address)

Progesterone

Changes in lipids and lipoproteins with long-term estrogen deficiency and hormone replacement therapy (Gambrell and Teran). 1991;165:307-17

Increased progesterone concentrations are necessary to suppress interleukin-2-activated human mononuclear cell cytotoxicity (Feinberg et al). 1991;165: 1872-6

Lymphocytes stimulate progesterone production by cultured human granulosa luteal cells (Emi et al). 1991;165:1469-74

The progesterone antagonist onapristone increases the effectiveness of oxytocin to produce delivery without changing the myometrial oxytocin receptor concentrations (Chwalisz et al). 1991;165:1760-70

Progesterone receptor; see Receptors, progesterone Progestogen

Gonadotropin-releasing hormone agonist and estrogenprogestogen replacement therapy (Gudmundsson et al) (Letter); (Barbieri) (Reply). 1991;165:1156-7

Prognathism

Pseudoprognathism—an auxiliary ultrasonographic sign for transvaginal ultrasonographic diagnosis of cleft lip and palate in the early second trimester (Bronshtein et al). 1991;165:1314-6

Prolactin

Animal model of uterine adenomyosis: Is prolactin a potent inducer of adenomyosis in mice? (Mori et al). 1991; 165:232-4 (Symposium)

Proline aminopeptidase assay

A new proline aminopeptidase assay for diagnosis of bacterial vaginosis (Schoonmaker et al). 1991;165: 737-42

Prolonged pregnancy; see Pregnancy, prolonged Prostaglandin antagonists

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep (Arnold-Aldea et al). 1991;165:185-90

Prostaglandin E2; see Dinoprostone

Prostaglandins

Do catechol estrogens participate in the initiation of labor? (Biswas et al). 1991;165:984-7

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep (Arnold-Aldea et al). 1991;165:185-90

The role of prostaglandins in detrusor instability (Bergman et al). 1991;165:1833-6

Prostanoids

Dose-related action of gonadotropin-releasing hormone on basal prostanoid production from the human term placenta (Kang et al). 1991;165:1771-6

Proteins

Free β-protein studies need confirmation (Goodlin) (Letter); (Macri et al) (Reply). 1991;165:779-80

Selective effects of preeclamptic sera on human endothelial cell procoagulant protein expression (Taylor et al). 1991;165:1705-10

Urinary protein/creatinine ratio before and during pregnancy in women with diabetes mellitus (Combs et al). 1991;165:920-3

December 1991 Am J Obstet Gynecol

Proteinuria

Urinary protein/creatinine ratio before and during pregnancy in women with diabetes mellitus (Combs et al). 1991;165:920-3

Proto-oncogenes

C-jun and jun-B oncogene expression during placental development (Dungy et al). 1991;165:1853-6

Expression and amplification of the HER-2/neu (c-erbB-2) protooncogene in epithelial ovarian tumors and cell lines (Tyson et al). 1991;165:640-6

Pseudoprognathism; see Prognathism

Psychological stress, see Stress

Psychology

Overview of social science and behavioral issues in natural family planning (Sharma and Spieler). 1991;165:2076 (Abstract)

Psychosexual aspects of natural family planning as revealed in the World Health Organization multicenter trial of the ovulation method and the New Zealand continuation study (France). 1991;165:2077 (Abstract)

Psychosocial factors in natural family planning: an overview (Sharma). 1991;165:2077 (Abstract)

Social science natural family planning issues (Sharma et al). 1991;165:2076-7 (Abstract)

Toward better marriages through natural family planning (Osmund-Ruiz). 1991;165:2076 (Abstract)

Psychophysiologic disorders

Correlation between sexual abuse and somatization in women with somatic and nonsomatic chronic pelvic pain (Reiter et al). 1991;165:104-9

Psychosocial support; see Social support

Psychosomatic disorders; see Psychophysiologic disorders Pudendal nerve

Pudendal neuralgia (Turner and Marinoff). 1991;165: 1233-6

Pueperium

Inappropriate secretion of antidiuretic hormone in Sheehan's syndrome: a rare cause of postpartum hyponatremia (Putterman et al). 1991;165:1330-3

Puerperium

Hemostatic wrapping of ruptured liver in two postpartum patients (Rittenberry et al). 1991;165:705-7

Incidence and risk factors associated with abnormal postpartum glucose tolerance in women with gestational diabetes (Catalano et al). 1991;165:914-9

Nifedipine pharmacokinetics and pharmacodynamics during the immediate postpartum period in patients with preeclampsia (Barton et al). 1991;165:951-4

Postpartum preeclampsia-induced shock and death: a report of three cases (Kalur et al). 1991;165:1362-8

Postpartum vaginal atrophy (Wisniewski and Wilkinson). 1991;165:1249-54

When do cardiovascular parameters return to their preconception values? (Capeless and Clapp). 1991;165:883-6

Pulmonary artery

Pulmonary-to-aorta diameter ratio in the normal and abnormal fetal heart (Comstock et al). 1991;165:1038-44

Pulmonary embolism

Extensive pulmonary embolism presenting as severe adult respiratory distress syndrome after surgical resection of a cornual pregnancy (tenHoopen et al). 1991;165:41-2

Pulmonary wedge pressure

Relationship between central venous pressure and pulmonary capillary wedge pressure in severely toxemic patients (Tellez). 1991;165:487 (Letter)

Purpura, thrombotic thrombocytopenic

Thrombotic thrombocytopenic purpura first seen as massive vaginal necrosis (Gallup et al). 1991;165:413-5

Pyelonephritis

Renal pelvicalyceal dilation in antepartum pyelonephritis: ultrasonographic findings (Twickler et al). 1991;165: 1115-9

Q

Quality of health care

The effect of supervision on program development and quality of services (St. Mart). 1991;165:2074 (Abstract)

A management needs assessment for African natural family planning programs: process and results (Pedersen). 1991;165:2073 (Abstract)

Our shield: competence with compassion (Laffitte). 1991;165:243-4 (Pres. address)

Service delivery part 2: elements necessary for success (Jennings et al). 1991;165:2073-4 (Abstract)

Targeting quality of care: a strategy for successful periodic abstinence services (Kopp). 1991;165:2074 (Abstract)

R

Radiation therapy; see Radiotherapy

Radioiodoestradiol

Prolonged clearance of intraperitoneal 16α -[125 I]iodo- 17β -estradiol in presence of ascites (Scharl et al). 1991;165:1847-53

Radiotherapy

Primary invasive vaginal carcinoma (Eddy et al). 1991;165:292-8

Receptors, epidermal growth factor-urogastrone

Cytologic localization of epidermal growth factor and its receptor in developing human placenta varies over the course of pregnancy (Ladines-Llave et al). 1991;165:1377-82

Measurement of human epidermal growth factor receptor in the endometrium during the menstrual cycle (Troche et al). 1991;165:1499-503

Receptors, estrogen

Effect of clomiphene citrate treatment on endometrial estrogen and progesterone receptor induction in women (Fritz et al). 1991;165:177-85

Receptors, interleukin-2

Changes in immunologic parameters in normal pregnancy and spontaneous abortion (MacLean et al). 1991;165:890-5

Receptors, progesterone

Effect of clomiphene citrate treatment on endometrial estrogen and progesterone receptor induction in women (Fritz et al). 1991;165:177-85

Recombinant 8 syndrome; see Chromosomes, human, pair 8 Recombinant tissue plasminogen activator; see Plasminogen activator, tissue-type

Recurrent spontaneous abortion; see Abortion, habitual Reference values

The evolution of reference methods to monitor ovulation: How well do current markers perform? (Collins). 1991;165:1994-6

Reid hypothesis

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis Volume 165 Number 6, Part 1

as a mechanism for diabetic teratogenesis (Finley and Norton). 1991;165:1661-6

Religion

Multifetal pregnancy reduction and disposal of untransplanted embryos in contemporary Jewish law and ethics (Grazi and Wolowelsky). 1991;165:1268-71 (Clin. opinion)

Renal agenesis

Renal agenesis in association with malformation of the female genital tract (Acién et al). 1991;165:1368-70

Renal circulation, animal

The effect of the inhibition of prostaglandin synthesis on renal blood flow in fetal sheep (Arnold-Aldea et al). 1991;165:185-90

Respiratory distress syndrome, adult

Extensive pulmonary embolism presenting as severe adult respiratory distress syndrome after surgical resection of a cornual pregnancy (tenHoopen et al). 1991;165: 41-9

Restriction fragment length polymorphisms

Genetic identification of pregnancies responsible for choriocarcinomas after multiple pregnancies by restriction fragment length polymorphism analysis (Osada et al). 1991;165:682-8

Retrograde menstruation; see Menstruation disorders Rh alloimmunization; see Rh isoimmunization Rh isoimmunization

Absence of hyperinsulinemia in isoimmunized fetuses treated with intravascular transfusion (Socol et al). 1991;165:1737-40

Enhanced sensitization after cordocentesis in a rhesusisoimmunized pregnancy (MacGregor et al). 1991;165: 382-3

Porencephalic cyst: a complication of fetal intravascular transfusion (Dildy et al). 1991;165:76-8

Rheography; see Plethysmography, impedance Rhesus hemolytic disease; see Erythroblastosis, fetal Rhesus-isoimmunization; see Rh isoimmunization Riley-Day syndrome; see Dysautonomia, familial Ringer's lactated solution; see Fluid therapy Risk factors

Cigarette smoking during pregnancy in relation to placenta previa (Williams et al). 1991;165:28-32

Double jeopardy: twin infant mortality in the United States, 1983 and 1984 (Fowler et al). 1991;165:15-22

Improving disclosure of smoking by pregnant women (Mullen et al). 1991;165:409-13

Spontaneous preterm birth: a case-control study (de Haas et al). 1991;165:1290-6

Ritodrine

Acute cutaneous vasculitis associated with prolonged intravenous ritodrine hydrochloride therapy (Bosnyak et al). 1991;165:427-8

Oral tocolysis with magnesium chloride: a randomized controlled prospective clinical trial (Ricci et al). 1991;165:603-10

RNA, messenger

Cellular localization of müllerian inhibiting substance messenger ribonucleic acid during human ovarian follicular development (Whitman and Pantazis). 1991;165: 1881-6

Inhibin subunits in human placenta: localization and messenger ribonucleic acid levels during pregnancy (Petraglia et al). 1991;165:750-8

Roman Catholic Church; see Catholicism

Rotation of fetus; see Version, fetal RU 486; see Mifepristone

S

Salpingitis

Increased inducibility of inflammatory mediators from peripheral blood mononuclear cells of women with salpingitis (Witkin et al). 1991;165:719-23

Recurrence of ectopic pregnancy: the role of salpingitis (Joesoef et al). 1991;165:46-50

Santiago Breastfeeding Promotion Program

Santiago Breastfeeding Promotion Program: preliminary results of an intervention study (Pérez and Valdés). 1991;165:2039-44

Screening, mass; see Mass screening

Second trimester; see Pregnancy trimester, second

Magnesium sulfate versus phenytoin for seizure prophylaxis in pregnancy-induced hypertension (Appleton et al). 1991;165:907-13

Septic abortion; see Abortion, septic

Sex

Maternal genital herpes and gender of offspring (Brown and Corey) (Letter); (McGregor) (Reply). 1991;165:784-5

Sex behavior

Overview of social science and behavioral issues in natural family planning (Sharma and Spieler). 1991;165:2076 (Abstract)

Sex education

Center for Research, Education, Service and Training's fertility education program for youth (Mascarenhas). 1991;165:2070 (Abstract)

Experiences and trends in natural family planning education and outreach (Rodriguez-Garcia et al). 1991;165: 2070-1 (Abstract)

Fertility education for young men (Burke). 1991;165:2071 (Abstract)

Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cohort (Klaus and Kardatzke). 1991;165:2071 (Abstract)

Sex preselection

Natural family planning and sex selection: Fact or fiction? (Gray). 1991;165:1982-4

Sexual abstinence

Knowledge and use of periodic abstinence (Vaessen). 1991;165:2077 (Abstract)

Making periodic abstinence more acceptable to natural family planning users (Uricchio). 1991;165:2075 (Abstract)

Sexual abuse; see Child abuse, sexual

Sexual partners

Treatment failure of genital condylomata acuminata in women: role of the male sexual partner (Krebs and Helmkamp). 1991;165:337-40

Sexually transmitted diseases

High risk of human papillomavirus infection and cervical squamous intraepithelial lesions among women with symptomatic human immunodeficiency virus infection (Vermund et al). 1991;165:392-400

A life-threatening sexually transmitted *Haemophilus influenzae* in septic abortion: a case report (Pinhas-Hamiel et al). 1991;165:66

Sheehan's syndrome; see Hypopituitarism

Shock

Postpartum preeclampsia-induced shock and death: a report of three cases (Kalur et al). 1991;165:1362-8

Shock, septic

Toxic shock syndrome: an update (Reingold). 1991;165: 1236-9

Shoulder dystocia; see Dystocia

Sister chromatid exchange

Sister chromatid exchange frequency in directly prepared cytotrophoblasts: demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes (Shulman et al). 1991;165:1877-80

Sleep apnea syndromes

Severe obstructive sleep apnea and associated snoring documented during external tocography (Sherer et al). 1991:165:1300-1

Small-for-gestational-age fetus; see Infant, small for gestational age

Smoking

Case report of myocardial infarction in labor (Menegakis and Amstey). 1991;165:1383-4

Cigarette smoking during pregnancy in relation to placenta previa (Williams et al). 1991;165:28-32

Effect of cigarette smoking on maternal airway function during pregnancy (Das et al). 1991;165:675-9

Improving disclosure of smoking by pregnant women (Mullen et al). 1991;165:409-13

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14

Sister chromatid exchange frequency in directly prepared cytotrophoblasts: demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes (Shulman et al). 1991;165:1877-80

Spontaneous preterm birth: a case-control study (de Haas et al). 1991;165:1290-6

Snoring

Severe obstructive sleep apnea and associated snoring documented during external tocography (Sherer et al). 1991;165:1300-1

Social sciences

Overview of social science and behavioral issues in natural family planning (Sharma and Spieler). 1991;165:2076 (Abstract)

Social science natural family planning issues (Sharma et al). 1991;165:2076-7 (Abstract)

Social support

Psychosocial support for maternal stress during pregnancy: effect on birth weight (Rothberg and Lits). 1991;165:403-7

Society for Gynecologic Investigation

Papers of the Society for Gynecologic Investigation. 1991;165:1639-938

Society of Perinatal Obstetricians

Transactions of the eleventh annual meeting of the Society of Perinatal Obstetricians. 1991;165:787-1125

Solvents

The three most common occupational exposures reported by pregnant women: an update (Bentur and Koren). 1991;165:429-37 (Curr. dev.)

Sonicaid System 8000

Automated analysis of near-term antepartum fetal heart rate in relation to fetal behavioral states: the Sonicaid System 8000 (Mantel et al). 1991;165:57-65

South Atlantic Association of Obstetricians and Gynecologists

Transactions of the fifty-third annual meeting of the South Atlantic Association of Obstetricians and Gynecologists. 1991;165:243-345

Special report

Special report. 1991;165:1126-55

Sperm

Human cervical mucus: research update (Katz). 1991;165:1984-6

Natural family planning: looking ahead (Queenan and Moghissi). 1991;165:1979-80

Spider venoms

Loxoscelism threatening pregnancy: five cases (Anderson). 1991;165:1454-6

Spina bifida cystica

Risk of open spina bifida (Hershey) (Letter); (Thornton) (Reply). 1991;165:1159

Spontaneous abortion; see Abortion

Sports

Endocrine effects in female weight lifters who self-administer testosterone and anabolic steroids (Malarkey et al). 1991;165:1385-90

Squamous cell carcinoma; see Carcinoma, squamous cell Staphylococcus aureus

Toxic shock syndrome: an update (Reingold). 1991;165:1236-9

Sterilization, tubal, animal

The interaction of electrosurgical bipolar forceps and generators on an animal model of fallopian tube sterilization (Tucker et al). 1991;165:443-9

Steroids

Adrenal and ovarian steroid hormone responses to gonadotropin-releasing hormone agonist treatment in polycystic ovary syndrome (Gonzalez et al). 1991;165:535-45

Steroid therapy for hydrops associated with antibody-mediated congenital heart block (Watson and Katz). 1991;165:553-4

Streptococcus agalactiae

Rapid enzyme-linked immunoassay tests for group B streptococcus infection (Green et al). 1991;165:486-7 (Letter)

Streptozotocin

Streptozocin-induced diabetes mellitus in the pregnant ewe (Dickinson et al). 1991;165:1673-7

Stress

Adverse psychologic consequences of positive cytologic cervical screening (Lerman et al). 1991;165:658-62

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14

Psychosocial support for maternal stress during pregnancy: effect on birth weight (Rothberg and Lits). 1991;165:403-7

Subchorionic hematoma; see Hematoma

Subcutaneous infusion pump; see Infusion pumps Substance abuse

Drug abuse screening of childbearing-age women in Alabama public health clinics (George et al). 1991;165:924-7

The effect of maternal cocaine use on the fetus: changes in antepartum fetal heart rate tracings (Tabor et al). 1991;165:1278-81

Prenatal behavioral risk screening by computer in a health maintenance organization—based prenatal care clinic (Lapham et al). 1991;165:506-14 Volume 165
Subject index 1971
Number 6, Part 1

Sulbactam

A rabbit model for bacterially induced preterm pregnancy loss: intervention studies with ampicillin-sulbactam (McDuffie et al). 1991;165:1568-74

Supervision; see Organization and administration

Supraventricular tachycardia; see Tachycardia, supraventricular

Surgery

A five-year statewide experience with congenital diaphragmatic hernia (Wenstrom et al). 1991;165:838-42

Splitting hairs about splitting muscles (Sutton) (Letter); (Helmkamp) (Reply). 1991;165:1575

Surgical instruments

The interaction of electrosurgical bipolar forceps and generators on an animal model of fallopian tube sterilization (Tucker et al). 1991;165:443-9

One-blade rotation of a persistent posterior vertex (Escamilla and Carlan). 1991;165:373-4

Surgical wound dehiscence

Uterine rupture during trial of labor after previous cesarean section (Farmer et al). 1991;165:996-1001

Sutures

Transvaginal removal of ovaries with endoloop sutures at the time of transvaginal hysterectomy (Hoffman). 1991:165:407-8

Swyer syndrome; see Gonadal dysgenesis, 46,XY Sympathomimetics

Myocardial necrosis in a newborn after long-term maternal subcutaneous terbutaline infusion for suppression of preterm labor (Fletcher et al). 1991;165:1401-4

Symptothermal method

Effectiveness and acceptability of the symptothermal method of natural family planning in Germany (Frank-Herrmann et al). 1991;165:2052-4

Efficacy of the symptothermal method of natural family planning in lactating women after the return of menses (Zinaman and Stevenson). 1991;165:2037-9

T

T-lymphocytes

Changes in immunologic parameters in normal pregnancy and spontaneous abortion (MacLean et al). 1991;165:890-5

Tachycardia, supraventricular

Treatment of fetal supraventricular tachycardia with flecainide acetate after digoxin failure (Kofinas et al). 1991;165:630-1

Tampons

Toxic shock syndrome: an update (Reingold). 1991; 165:1236-9

Teaching materials

Client teaching materials for francophone Africa (Ecochard). 1991;165:2072 (Abstract)

Experiences in the field: Confederacao Nacional de Centros de Planejamento Natural da Familia, Brazil (Sogayar). 1991;165:2071 (Abstract)

Introduction of natural family planning information into multimethod materials for trainers (Lea and Murphy). 1991;165:2071 (Abstract)

Issues in the development and dissemination of training and educational materials (Schaefer). 1991;165:2071 (Abstract)

Materials development, testing, and evaluation: an overview (Zimmerman and Bartlett). 1991;165:2071 (Abstract)

Materials development in Zambia: concept versus reality (Tafira). 1991;165:2071 (Abstract)

Materials for the modified mucus method (Dorairaj). 1991;165:2072 (Abstract)

Materials in the United States: an example from Los Angeles (Minervini). 1991;165:2072 (Abstract)

Materials translation: Is that really what you want to say? (Bowen and Bowen). 1991;165:2071 (Abstract)

Service delivery part 1: current programs and strategies for expansion (Mejia et al). 1991;165:2072-3 (Abstract)

Training and educational materials (Schaefer et al). 1991;165:2071-2 (Abstract)

Teen STAR Program

Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cohort (Klaus and Kardatzke). 1991;165:2071 (Abstract)

Temperature

The changing thermal response to endurance exercise during pregnancy (Clapp). 1991;165:1684-9

Teratogens

Effects of hyperglycemia on mitochondrial morphology in the region of the anterior neuropore in the explanted rat embryo model: evidence for a modified Reid hypothesis as a mechanism for diabetic teratogenesis (Finley and Norton). 1991;165:1661-6

Terbutaline

Effects of magnesium and terbutaline on contractility and K⁺ uptake in isolated human uterine muscle (Skajaa et al). 1991;165:1543-51

Myocardial necrosis in a newborn after long-term maternal subcutaneous terbutaline infusion for suppression of preterm labor (Fletcher et al). 1991;165:1401-4

Terconazole

The in vitro activity of terconazole against yeasts: its topical long-acting therapeutic efficacy in experimental vaginal candidiasis in rats (Van Cutsem). 1991;165:1200-€

Mode of action of anti-Candida drugs: focus on tercenazole and other ergosterol biosynthesis inhibitors (Vanden Bossche and Marichal). 1991;165:1193-9

Termination of pregnancy; see Abortion

Testicular determining factor

The presence of the testicular determining sequence, SRY, in 46,XY females with gonadal dysgenesis (Swyer syndrome) (Behzadian et al). 1991;165:1887-90

Testosterone

Endocrine effects in female weight lifters who self-administer testosterone and anabolic steroids (Malarkey et al). 1991;165:1385-90

Single and multiple administration of a new triphasic oral contraceptive to women: pharmacokinetics of ethinyl estradiol and free and total testosterone levels in serum (Kuhnz et al). 1991;165:596-602

Therapeutic termination of pregnancy; see Abortion, therapeutic

Thermal response; see Temperature

Third trimester of pregnancy; see Pregnancy trimester, third Thoracic duct, animal

Left thoracic duct lymph flow responses to angiotensin II or atrial natriuretic factor infusion in the ovine fetus (Brace and Andres). 1991;165:1607-13

Thrombocytopenia

Obstetric complications in a patient with Bernard-Soulier syndrome (Peng et al). 1991;165:425-6

Thrombophlebitis

Administration of heparin by subcutaneous infusion with a programmable pump (Floyd et al). 1991;165:931-3

Effect of pregnancy on the accuracy of light-reflection rheography (Allbert et al). 1991;165:1745-7

Ultrasonographic diagnosis of symptomatic deep venous thrombosis in pregnancy (Polak and Wilkinson). 1991;165:625-9

Thromboplastin

Amniotic fluid contains tissue factor, a potent initiator of coagulation (Lockwood et al). 1991;165:1335-41

Thrombotic thrombocytopenic purpura; see Purpura, thrombotic thrombocytopenic

Thromboxanes

The effect of the menstrual cycle and of decompression stress on arachidonic acid—induced platelet aggregation and on intrinsic platelet thromboxane production in women compared with men (Markham et al). 1991;165:1821-9

Endothelin-1-induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation (Myatt et al). 1991;165:1717-22

The imbalance between thromboxane and prostacyclin in preeclampsia is associated with an imbalance between lipid peroxides and vitamin E in maternal blood (Wang et al). 1991;165:1695-700

Maternal levels of prostacyclin, thromboxane, vitamin E, and lipid peroxides throughout normal pregnancy (Wang et al). 1991;165:1690-4

Simultaneous measurements of prostacyclin and thromboxane metabolites during the menstrual cycle (Presser et al). 1991;165:647-51

Tissue culture

Detection of *Chlamydia trachomatis* endocervical infection in asymptomatic and symptomatic women: comparison of deoxyribonucleic acid probe test with tissue culture (Yang et al). 1991;165:1444-53

Tissue factor; see Thromboplastin

Tissue plasminogen activator; see Plasminogen activator, tissue-type

Tocodynamometry; see Cardiotocography Tocography; see Cardiotocography

Tocolysis

A case report of massive vulvar edema during tocolysis of preterm labor (Brittain et al). 1991;165:420-2

Oral tocolysis with magnesium chloride: a randomized controlled prospective clinical trial (Ricci et al). 1991;165:603-10

Toxemia; see Pregnancy toxemias

Transactions

Transactions of the eleventh annual meeting of the Society of Perinatal Obstetricians. 1991;165:787-1125

Transactions of the fifty-third annual meeting of the South Atlantic Association of Obstetricians and Gynecologists. 1991;165:243-345

Transforming growth factor β

Transforming growth factor-β₁ expression during placental development (Dungy et al). 1991;165:853-7

Translations

Materials translation: Is that really what you want to say? (Bowen and Bowen). 1991;165:2071 (Abstract)

Transvaginal echocardiography; see Echocardiography Transvaginal hysterectomy; see Hysterectomy, vaginal

Transvaginal ultrasonography; see Ultrasonography, prenatal

Trichomonas vaginitis

Epidemiology of vaginitis (Kent). 1991;165:1168-76 Trichomoniasis: trends in diagnosis and management (Lossick and Kent). 1991;165:1217-22

Trisomy

Are choroid plexus cysts an indication for second-trimester amniocentesis? (Achiron and Mashiach) (Letter); (Benacerraf) (Reply). 1991;165:239-41

The effect of trisomy 18 on transverse cerebellar diameter (Hill et al). 1991;165:72-5

Trophoblastic tumor

The prevalence of recurrent spontaneous abortions, cancer, and congenital anomalies in the families of couples with recurrent spontaneous abortions or gestational trophoblastic tumors (Ho et al). 1991;165:461-6

Trophoblasts

Expression of extracellular matrix—degrading metalloproteinases by cultured human cytotrophoblast cells: effects of cell adhesion and immunopurification (Bischof et al). 1991;165:1791-801

Sister chromatid exchange frequency in directly prepared cytotrophoblasts: demonstration of in vivo deoxyribonucleic acid damage in pregnant women who smoke cigarettes (Shulman et al). 1991;165:1877-80

Transforming growth factor-β, expression during placental development (Dungy et al). 1991;165:853-7

Trophoblast from anembryonic pregnancy has both a maternal and a paternal contribution to its genome (Henderson et al). 1991;165:98-102

Truth disclosure

Improving disclosure of smoking by pregnant women (Mullen et al). 1991;165:409-13

Tryptophan

Tryptophan and neutral amino acids in premenstrual syndrome (Rapkin et al). 1991;165:1830-3

Tumor necrosis factor

Increased inducibility of inflammatory mediators from peripheral blood mononuclear cells of women with salpingitis (Witkin et al). 1991;165:719-23

Tumor necrosis factor-α and interleukin-1β production by human fetal Kupffer cells (Kutteh et al). 1991;165:112-90

Twins

Double jeopardy: twin infant mortality in the United States, 1983 and 1984 (Fowler et al). 1991;165:15-22

The origin of brain lesions in survivors of twin gestations complicated by fetal death (Gonen). 1991;165:1897-8 (Letter)

Quantification of cervical change: relationship to preterm delivery in the multifetal gestation (Newman et al). 1991;165:264-71

Twin delivery: influence of the presentation and method of delivery on the second twin (Adam et al). 1991;165: 23-7

Twin gestation: influence of placentation on fetal growth (Pridjian et al). 1991;165:1394-401

Ultrasonographic diagnosis of congenital anomalies in twins (Allen et al). 1991;165:1056-60

U

Ultrasonography

Does the brachial artery Doppler flow velocity waveform reflect changes in downstream impedance? (Fairlie and Walker). 1991;165:1741-4

- Renal pelvicalyceal dilation in antepartum pyelonephritis: ultrasonographic findings (Twickler et al). 1991;165: 1115-9
- Ultrasonographic diagnosis of symptomatic deep venous thrombosis in pregnancy (Polak and Wilkinson). 1991;165:625-9
- Ultrasonographic patterns of ovarian activity during breast-feeding (Flynn et al). 1991;165:2027-31

Ultrasonography, prenatal; see also Prenatal diagnosis

- Arterial blood flow velocity waveforms of the pelvis and lower extremities in normal and growth-retarded fetuses (Mari). 1991;165:143-51
- The cheek-to-cheek diameter in the ultrasonographic assessment of fetal growth (Abramowicz et al). 1991;165:846-52
- Comparison of humerus length with femur length in fetuses with Down syndrome (Rodis et al). 1991;165: 1051-6
- Congenital hydronephrosis: correlation of fetal ultrasonographic findings with infant outcome (Corteville et al). 1991;165:384-8
- Embryonic ultrasonographic measurements: crown-rump length revisited (Goldstein). 1991;165:497-501 (Clin. opinion)
- Evaluation of obstetric ultrasonography at the first prenatal visit (Barrett and Brinson). 1991;165:1002-5
- Fetal abdominoscrotal hydrocele (Sasidharan et al). 1991;165:1353-5
- Fetal atrioventricular and outflow tract flow velocity waveforms during normal second half of pregnancy (van der Mooren et al). 1991;165:668-74
- The fetal-pelvic index: a method of identifying fetal-pelvic disproportion in women attempting vaginal birth after previous cesarean delivery (Thurnau et al). 1991;165: 353-8
- First report: prenatal diagnosis of a true knot (Collins). 1991;165:1898 (Letter)
- First report: prenatal diagnosis of long cord (Collins). 1991;165:1900-1 (Letter)
- Giacomello's observation and nuchal cords (Collins) (Letter); (Giacomello) (Reply). 1991;165:1895
- Intrapartum ultrasonographic estimates of fetal weight by the house staff (Platek et al). 1991;165:842-5
- Maternal hemodynamics in pregnancy (Baumann and Huch) (Letter); (Ikeda and Mori) (Reply). 1991;165:237-8
- Predictive value of early embryonic cardiac activity for pregnancy outcome (Merchiers et al). 1991;165:11-4
- Pseudoprognathism—an auxiliary ultrasonographic sign for transvaginal ultrasonographic diagnosis of cleft lip and palate in the early second trimester (Bronshtein et al). 1991;165:1314-6
- Transvaginal fetal echocardiography in early pregnancy: normative data (Dolkart and Reimers). 1991;165: 688.01
- Transverse cerebellar diameter: a useful predictor of gestational age for fetuses with asymmetric growth retardation (Lee et al). 1991;165:1044-50
- Ultrasonographic diagnosis of congenital anomalies in twins (Allen et al). 1991;165:1056-60
- Ultrasonographic screening for the Down syndrome fetus (Lockwood et al). 1991;165:349-52 (Clin. opinion)
- Ultrasonographic visualization of endometrial vascularity with ectopic pregnancy (Cadkin and Applebaum). 1991;165:236 (Letter)

- Uterine and fetal Doppler flow changes after intravaginal prostaglandin E₂ therapy for cervical ripening (Rayburn et al). 1991;165:125-6
- What is a low-lying placenta? (Oppenheimer et al). 1991;165:1036-8

Umbilical arteries

- Doppler flow velocities in single umbilical arteries (Duerbeck et al). 1991;165:1120-2
- The relationship between umbilical artery Doppler velocimetry and fetal biometry (Scorza et al). 1991;165: 1013-9

Umbilical arteries, animal

Fetal hypertension induced by norepinephrine infusion and umbilical artery flow velocity waveforms in fetal sheep (van Huisseling et al). 1991;165:450-5

Umbilical cord

- Fetal hiccups and the umbilical ring (Collins). 1991; 165:1161 (Letter)
- First report: prenatal diagnosis of a true knot (Collins). 1991;165:1898 (Letter)
- First report: prenatal diagnosis of long cord (Collins). 1991;165:1900-1 (Letter)
- Funic reduction for the management of umbilical cord prolapse (Barrett). 1991;165:654-7
- Giacomello's observation and nuchal cords (Collins) (Letter); (Giacomello) (Reply). 1991;165:1895
- Relationship between fetal biophysical activities and umbilical cord blood gas values (Vintzileos et al). 1991;165:707-

Umbilical veins

An endothelial cell model for the investigation of the molecular regulation of fetal vascular tone (Dudley et al). 1991;165:1723-6

Urinary incontinence

Assessment of Kegel pelvic muscle exercise performance after brief verbal instruction (Bump et al). 1991;165:322-9

Urinary proteins; see Proteins

Urinary tract infections

- Effectiveness of antibiotic prophylaxis in preventing bacteriuria after multichannel urodynamic investigations: a blind, randomized study in 124 female patients (Baker et al). 1991;165:679-81
- Renal pelvicalyceal dilation in antepartum pyelonephritis: ultrasonographic findings (Twickler et al). 1991;165: 1115-9

Urine

Oligohydramnios: antepartum fetal urine production and intrapartum fetal distress (Groome et al). 1991;165:1077-80

Uterine activity; see Uterine contraction

Uterine cervix; see Cervix uteri

Uterine contraction

- The effect of amnioinfusion on uterine pressure and activity (Miyazaki) (Letter); (Posner) (Reply). 1991;165: 1898-9
- Effects of magnesium and terbutaline on contractility and K⁺ uptake in isolated human uterine muscle (Skajaa et al). 1991;165:1543-51
- Extended longitudinal study of uterine activity among lowrisk women (Main et al). 1991;165:1317-22
- Fetal movement during labor (Reddy et al). 1991;165:1073-6
- Home monitoring of uterine contractility (Rhoads et al). 1991;165:2-6 (Clin. opinion)

Uterine contraction-cont'd

Multicenter randomized clinical trial of home uterine activity monitoring for detection of preterm labor (Mou et al). 1991;165:858-66

Patterns of uterine activity after intravaginal prostaglandin E₂ during preinduction cervical ripening (Miller et al). 1991;165:1006-9

Qualitative evaluation of uterine contractions recorded by a double guard-ring tocodynamometer (Shinmoto et al). 1991;165:1282-6

Uterine activity after preterm premature rupture of the membranes (Campbell et al). 1991;165:422-5

Uterine contraction, animal

Circadian myometrial and endocrine rhythms in the pregnant rhesus macaque: effects of constant light and timed melatonin infusion (Matsumoto et al). 1991;165:1777-84

Forward shift in the initiation of the nocturnal estradiol surge in the pregnant baboon: Is this the genesis of labor? (Wilson et al). 1991;165:1487-98

Inhibition of oxytocin-induced uterine contractions by an oxytocin antagonist in the pregnant baboon (Wilson et al). 1991;165:456-60

Uterine neoplasms

Effects of peritoneal macrophages from patients with endometriosis on the proliferation of endometrial carcinoma cell line ECC-1 (Zhang et al). 1991;165: 1842-6

Endometrial morphology in asymptomatic postmenopausal women (Archer et al). 1991;165:317-22

Specific binding sites for insulin and insulin-like growth factor I in human endometrial cancer (Nagamani et al). 1991;165:1865-71

Ultrastructural study of glandular epithelium in adenomyosis in comparison with those of proliferative endometrium and well-differentiated endometrial cancer (Hayata). 1991;165:225-8 (Symposium)

Uterine rupture

Uterine rupture at term pregnancy with the use of intracervical prostaglandin E₂ gel for induction of labor (Maymon et al). 1991;165:368-70

Uterine rupture during trial of labor after previous cesarean section (Farmer et al). 1991;165:996-1001

Uterus, anatomy and histology

Histologic study of endometriosis and examination of lymphatic drainage in and from the uterus (Ueki). 1991;165:201-9 (Symposium)

Subserosal adenomyosis: a possible variant of pelvic endometriosis (Sakamoto). 1991;165:198-201 (Symposium)

Uterus, blood supply

Relaxation of the human uterine artery by atrial natriuretic peptide is independent of the endothelium (Bodelsson et al). 1991;165:483-4 (Letter)

V

Vagina, embryology

Renal agenesis in association with malformation of the female genital tract (Acién et al). 1991;165:1368-70

Vagina, microbiology

Bacterial vaginosis: current review with indications for asymptomatic therapy (Thomason et al). 1991;165:1210-

The vaginal ecosystem (Mårdh). 1991;165:1163-8

Vaginal birth; see Delivery

Vaginal birth after cesarean

External cephalic version after previous cesarean section (Flamm et al). 1991;165:370-2

The fetal-pelvic index: a method of identifying fetal-pelvic disproportion in women attempting vaginal birth after previous cesarean delivery (Thurnau et al). 1991; 165:353-8

Uterine rupture during trial of labor after previous cesarean section (Farmer et al). 1991;165:996-1001

Vaginal diseases

Adjunctive clindamycin therapy for preterm labor: results of a double-blind, placebo-controlled trial (McGregor et al). 1991;165:867-75

A new proline aminopeptidase assay for diagnosis of bacterial vaginosis (Schoonmaker et al). 1991;165: 737-42

Postpartum vaginal atrophy (Wisniewski and Wilkinson). 1991;165:1249-54

Thrombotic thrombocytopenic purpura first seen as massive vaginal necrosis (Gallup et al). 1991;165:413-5

The vaginal ecosystem (Mårdh). 1991;165:1163-8

Vaginal diseases, animal

Fungal morphology after treatment with itraconazole as a single oral dose in experimental vaginal candidosis in rats (Jansen et al). 1991;165:1552-7

Vaginal neoplasms

Laser vaporization of grade 3 vaginal intraepithelial neoplasia (Hoffman et al). 1991;165:1342-4

Primary invasive vaginal carcinoma (Eddy et al). 1991;165:292-8

Vaginal cancer: the role of infectious and environmental factors (Merino). 1991;165:1255-62

Vaginal smears

Adverse psychologic consequences of positive cytologic cervical screening (Lerman et al). 1991;165:658-62

Trichomoniasis: trends in diagnosis and management (Lossick and Kent). 1991;165:1217-22

Vaginitis

Bacterial vaginosis: current review with indications for asymptomatic therapy (Thomason et al). 1991;165:1210-7

Epidemiology of vaginitis (Kent). 1991;165:1168-76

A new proline aminopeptidase assay for diagnosis of bacterial vaginosis (Schoonmaker et al). 1991;165:737-42

Nonbarrier contraceptives and vaginitis and vaginosis (Roy). 1991;165:1240-4

The vaginal ecosystem (Mårdh). 1991;165:1163-8

Varicella-zoster virus

In utero diagnosis of congenital varicella zoster virus infection by chorionic villus sampling and polymerase chain reaction (Isada et al). 1991;165:1727-30

Vascular resistance, animal

Fetal hypertension induced by norepinephrine infusion and umbilical artery flow velocity waveforms in fetal sheep (van Huisseling et al). 1991;165:450-5

Vascular smooth muscle; see Muscle, smooth, vascular Vasculitis

Placental pathologic findings in preterm birth (Salafia et al). 1991;165:934-8. 1991;165:1948 (Correction)

Vasculitis, allergic cutaneous

Acute cutaneous vasculitis associated with prolonged intra-

venous ritodrine hydrochloride therapy (Bosnyak et al). 1991;165:427-8

Vasoconstriction

Endothelin-1-induced vasoconstriction is not mediated by thromboxane release and action in the human fetal-placental circulation (Myatt et al). 1991;165: 1717-22

Vasodilation, animal

Enhanced endothelium-derived relaxing factor activity in pregnant, spontaneously hypertensive rats (Ahokas et al). 1991;165:801-7

Vasodilator agents

Atrial natriuretic peptide: A vasodilator of the fetoplacental circulation? (Kingdom et al). 1991;165:791-800

Vasopressins

Inappropriate secretion of antidiuretic hormone in Sheehan's syndrome: a rare cause of postpartum hyponatremia (Putterman et al). 1991;165:1330-3

Oral-nasal membranes are not the major route for fetal absorption of amniotic fluid arginine vasopressin (Gilbert et al). 1991;165:1614-20

Vasopressin and operative hysteroscopy in the management of delayed postabortion and postpartum bleeding (Townsend et al). 1991;165:616-8

Vasopressin pack for treatment of bleeding after myoma resection (Townsend). 1991;165:1405-7

Venous pressure

Relationship between central venous pressure and pulmonary capillary wedge pressure in severely toxemic patients (Tellez). 1991;165:487 (Letter)

Venous thrombosis; see Thrombophlebitis Version, fetal

External cephalic version after previous cesarean section (Flamm et al). 1991;165:370-2

One-blade rotation of a persistent posterior vertex (Escamilla and Carlan). 1991;165:373-4

Vibration, animal

Effects of vibration frequency and tissue thickness on intrauterine sound levels in sheep (Richards et al). 1991;165:438-42

Vibroacoustic stimulation; see Acoustic stimulation Video display terminals; see Computer systems Videolaseroscopy; see Laser surgery

Villositis

Placental pathologic findings in preterm birth (Salafia et al). 1991;165:934-8. 1991;165:1948 (Correction)

Violence

An epidemic of antiabortion violence in the United States (Grimes et al). 1991;165:1263-8 (Clin. opinion)

Visual test; see Diagnostic tests

Vitamin E

The imbalance between thromboxane and prostacyclin in preeclampsia is associated with an imbalance between lipid peroxides and vitamin E in maternal blood (Wang et al). 1991;165:1695-700

Maternal levels of prostacyclin, thromboxane, vitamin E, and lipid peroxides throughout normal pregnancy (Wang et al). 1991;165:1690-4

Vulvar diseases

A case report of massive vulvar edema during tocolysis of preterm labor (Brittain et al). 1991;165:420-

Pudendal neuralgia (Turner and Marinoff). 1991;165: 1233-6

Vulvar vestibulitis syndrome: an overview (Marinoff and Turner). 1991;165:1228-33

Vulvar neoplasms

Vulvar. squamous cell carcinoma and papillomaviruses: Two separate entities? (Andersen et al). 1991;165:329-36

Vulvitis

Vulvitis and vulvovaginitis: cutaneous considerations (McKay), 1991;165:1176-82

Vulvovaginitis

Mycotic vulvovaginitis: a broad overview (Horowitz). 1991;165:1188-92

Vulvitis and vulvovaginitis: cutaneous considerations (McKay). 1991;165:1176-82

Vulvovaginitis: the role of patient compliance in treatment success (Nixon). 1991;165:1207-9

W

Water-electrolyte balance, animal

Fetal cardiovascular and fluid responses to maternal volume loading with lactated Ringer's or hypotonic solutions (Powers and Brace). 1991;165:1504-15

Weight lifting

Endocrine effects in female weight lifters who self-administer testosterone and anabolic steroids (Malarkey et al). 1991;165:1385-90

White blood cell count; see Blood cell count Wilson's disease; see Hepatolenticular degeneration Wood preservatives

Prolonged exposure to wood preservatives induces endocrine and immunologic disorders in women (Gerhard et al). 1991;165:487-8 (Letter)

World Health Organization

Psychosexual aspects of natural family planning as revealed in the World Health Organization multicenter trial of the ovulation method and the New Zealand continuation study (France). 1991;165:2077 (Abstract)

World Health Organization's policy considerations in natural family planning (Mehra). 1991;165:2075 (Abstract)

Wound healing, animal

Reduction of primary posttraumatic adhesion formation with the prostacyclin analog iloprost in a rodent model (Steinleitner et al). 1991;165:1817-20

Y

Yeasts

The in vitro activity of terconazole against yeasts: its topical long-acting therapeutic efficacy in experimental vaginal candidiasis in rats (Van Cutsem). 1991;165: 1200-6

Z

Zambia

Creating a demand for scientific natural family planning: the Zambian experience (Tafira). 1991;165:2070 (Abstract)

Evaluation of natural family planning programs in Liberia and Zambia (Kambic et al). 1991;165:2078 (Abstract)

Factors related to autonomy and discontinuation of use of natural family planning for women in Liberia and Zambia (Kambic and Gray). 1991;165:2060-2

Zambia—cont'd

Materials development in Zambia: concept versus reality (Tafira). 1991;165:2071 (Abstract)

Zona pellucida

Partial dissection of the zona pellucida of frozen-thawed

human embryos may enhance blastocyst hatching, implantation, and pregnancy rates (Tucker et al). 1991;165:341-5

Southern California Permanente Medical Group (SCPMG) provides their physicians with an opportunity for professional fulfillment in the following ways:

Commitment to Education

- Over 40% of SCPMG physicians have faculty appointments
- OB/GYN residents from UCLA, Harbor-UCLA, UC Irvine, UC San Diego, USC and Loma Linda University rotate through our medical centers
- 4 hours paid CME each week

Quality Clinical Practice

- Diverse patient population and a wide range of pathology
- Modern medical centers and equipment
- Highly competitive income and benefits package including paid malpractice

Notable OB/GYN Achievements by SCPMG Physicians

- Developed the "Miya Hook" surgical tool
- Developed the Amnio-Infusion procedure
- Authored the world's largest VBAC study Birth After Cesarean

For more information, send your CV to: Irwin P. Goldstein, MD, Associate Medical Director, SCPMG Dept. 006, Walnut Center, Pasadena, CA 91188-8013.

Generalist Obstetrician/Gynecologist Maternal/Fetal Medicine Subspecialist **Gynecologic Oncologist Faculty Positions**

The James H. Quillen College of Medicine of East Tennessee State University (ETSU) is seeking a board certified/eligible General Obstetrician/Gynecologist and a board certified/eligible Maternal/Fetal Medicine (Perinatology) subspecialist and a board 'certified/eligible. Gynecologic Oncologist. These positions offer an excellent opportunity combining research, teaching and private practice with a faculty position at the Assistant/Associate Professor level. Salaries are very competitive and fringe benefits are excellent. The Medical School is located in the Tri-Cities area of Northeast Tennessee in a beautiful section of the Appalachians and within sight of the Blue Ridge Mountains. The area has excellent hunting, fishing, and camping with multiple ski resorts at your doorstep. The Tri-Cities combines good schools and rural living in a safe, beautiful environment. Yet, the medical referral base consists of 1.3 million people within a 50 mile radius of the Medical School. Send curriculum vitae to:

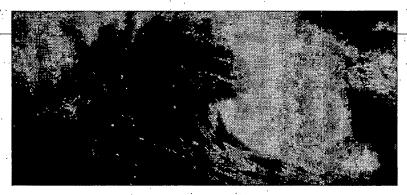

> Frederick R. Jelovsek, M.D. Professor and Chairman, Dept. OB/GYN James H. Quillen College of Medicine East Tennesee State University P.O. Box 19570A Johnson City, TN 37614-0002

> > ETSU is an AA/EO employer.

PERINATOLOGIST Philadelphia, PA

FRANKFORD HOSPITAL seeks a 3rd Perinatologist for its expanding Perinatal Center. Require consultations, ultrasonography and physician, resident and nurse teaching. Encourage clinical research. With 392 beds, 2000 + deliveries, we are a major teaching affiliate of the Medical College of PA. Through association with two University Medical Centers, the perinatologist will be exposed to 20 residents and 6000 + births. Private practice with a strong academic environment. Academic rank commensurate with experience and achievements. Salary and benefits package extremely competitive. Incentive compensation available. Send C.V. to FRANKFORD PERINATAL CENTER, Suite 102, Torresdale Campus Medical Building, Knights & Red Lion Roads, Philadelphia, PA 19114. EOE

Frankford Perinatal

The power of the inevitable

The health care crisis in this country makes change inevitable. There is one organization that recognized this fact nearly 50 years ago. Group Health Cooperative is the largest consumergoverned HMO is the country. Our medical staff is self-managed and sets its own practices and guidelines. We can offer financial security, strong collegial relationships, continuing education, and, most importantly, diverse practice opportunities designed to fit the individual's practice style, needs and desires.

Feel for yourself the power of the inevitable. For further information about becoming a Group Health OB/GYN, call (800) 543-9323.

Immediate need for BC/BE OB/GYN. Join one other OB/GYN in nine member multispecialty group. Office is located on campus of 167-bed hospital in Central Illinois community of 12,000 with a county population of 32,000. Just 30 minutes from shopping, restaurants, and cultural events in the capital, Springfield. Partnership buy-in after and second \$200,000 salary, incentive, and benefits. Send CV or call:

GREG STELMACH JACKSON AND COKER, INC. 115 Perimeter Center Place Suite 380 11266 Atlanta, GA 30346 Tel. 1-800-544-1987

This established physician practice is offering an excellent opportunity for a BC/BE obstetrician. We're located in beautiful Southeastern New Hampshire, where you'll discover the ideal lifestyle. The location offers proximity to mountains, lakes and seacoast, plus a wealth of cultural attractions. It all adds up to a very healthy family environment.

We're offering a competitive salary, and occurrence malpractice premiums are fully paid. What's more, there's an ownership opportunity after the initial employment period. The position will be available by

July, 1992 or earlier.

This position has a lot to offer. In a state that has everything.

The group is affiliated with a 330-bed hospital with a Level II Nursery in one of scenic New England's fastest-

growing areas, just one hour from Boston. Reply with CV to: Office of Physician Services, Catholic Medical Center, 100 McGregor Street, Manchester, NH 03102. (603) 626-2879. This could be everything you always wanted.

SHOCK YOUR FAMILY & FRIENDS!

Tell them you're looking at practicing in eastern North Dakota or western Minnesota! Our countrypolitan lifestyle includes commutes of up to 9 minutes, 6car traffic jams, unlocked doors, exceptional schools, bagging the limit in fish and game or just dangling your feet off the dock. The Dakota Clinic is a 154-person multispecialty group looking for OB/ GYN physicians. Specific sites include Fargo and Jamestown, North Dakota, as well as Detroit Lakes or Park Rapids, Minnesota. Excellent salary and benefits with stockholder opportunity after two years. There are minimal buy-in requirements. To receive our video and community practice information kit, call Dick Reis at 1-800-342-4926, or write: Dick Reis, Manager, Recruiting, Dakota Clinic, Ltd., 1702 South University Drive, Fargo, ND 58103.

RHODE ISLAND

OBSTETRICS/GYNECOLOGY

Excellent opportunity for BC/BE physicians to establish solo or group practice in our progressive 359 bed acute care hospital located in a suburban coastal community with easy access to New England cultural and recreational activities. Kent County Memorial Hospital offers a family centered maternity care unit while endorsing the LDRP concept. Our service area borders Newport... We're one hour from Boston and an easy drive to New York City. Competitive financial package including income guarantee, practice establishment assistance, relocation expenses, etc. Please send C.V. to Robert E. Baute, M.D., Medical Director, Kent County Memorial Hospital, 455 Toll Gate Road, Warwick, Rhode Island 02886.

The best of Rhode Island starts here... **Kent County Memorial Hospital**

OBSTETRICIAN/ GYNECOLOGIST

Unique opportunity for qualified OB/GYN physicians to join the staff of the Medical Center of Delaware as a member of the full time faculty beginning July 1, 1992.

Responsibilities include treating patients in area clinics, supervision of residents, and an opportunity to establish a private practice.

We offer a generous salary and benefits package which includes Professional Liability Insurance, vacation, health insurance coverage, dental and prescription plans, and paid conference time. Newark, Delaware is in close proximity to Philadelphia and Baltimore, sports, cultural events, theatre and shopping.

If you like living in a great area, a diversity of patients and responsibilities, and a promising future, then direct your inquiries and curriculum vitae to:

Medical Center of Delaware c/o Garrett H. C. Colmorgen, M.D. Obstetrics and Gynecology Maternal-Fetal Medicine 4755 Ogletown-Stanton Road P.O. Box 6001 Newark, DE 19718

ACADEMIC POSITIONS AVAILABLE MATERNAL-FETAL MEDICINE MEDICAL UNIVERSITY OF SOUTH CAROLINA

The Department of Obstetrics and Gynecology invites applications for Board eligible/Board Certified maternal-fetal medicine specialists. The Section supports a fellowship training program and provides major clinical and research opportunities in high-risk obstetrics, multifetal gestations, myometrial physiology, immunology, ultrasonography and fetal echocardiography. A free-standing Prenatal Diagnostic Center has been developed by the Section to provide outpatient genetic services, prenatal diagnostic testing, fetal assessment and consultative ultrasound. The Prenatal Center will use two recently purchased Acuson 128XP-10 computed sonography imaging systems.

Recruitment is for Assistant/Associate Professor level faculty. Interest and experience in ultrasonography and prenatal diagnosis is preferred. Academic appointment and excellent compensation package will be commensurate with training and experience. All inquires will be confidential.

IMPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

INDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

INDICATIONS AND USAGE: PREVENTION OF PREMARCY.

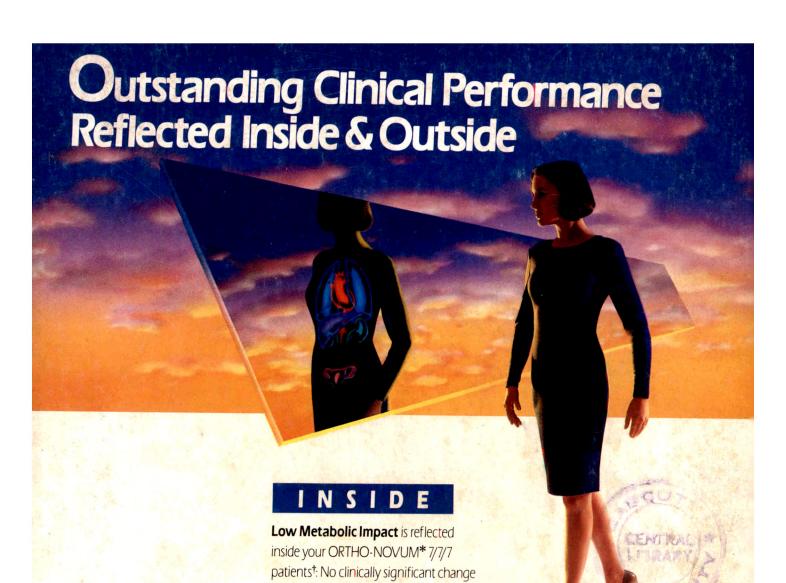

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophilebitis or thromboembolic disorders. 2. A past history of deep vein thrombophilebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contracep-tive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strength additional and to marke.

Cigarette moking increases the risk of motivate cardiovasular size effects from varia contraceptives and the part of the part

that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4 HEPATIC NEOPLA-SIA Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptive. Oral contraceptives should be discontinued there is unexplained partial or complete loss of vision, onset of proptosis or diplopia, appliedema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior US and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches shall not be permission users. SOULAR LESIONS There have been climical case reports of refinal introduciss associated with the use of oral contraceptives. Oral contraceptives should be described introducing the contraceptive or contraceptives or contraceptives or contraceptives or contraceptives or contraceptives or contraceptives or contraceptives. Abstracts of Nine Sessions to be Published by Georgetown University	2069
	2000

American Journal of Obstetrics and Gynecology

Founded in 1920

volume 165 number 6 part 2 DECEMBER 1991

Introduction

A conference on "Natural Family Planning: Current Knowledge and New Strategies for the 1990s" was held at Georgetown University, Washington, D.C., on December 11-14, 1990. The conference was sponsored by the Institute for International Studies in Natural Family Planning, based in the Department of Obstetrics and Gynecology in the Georgetown University School of Medicine, and by the World Health Organization. Support was provided by the United States Agency for International Development through a cooperative agreement with the Georgetown Institute.

The purpose of the conference was to provide a forum for researchers, trainers, program managers, communicators, and educators to share the results of their work and chart new directions for increasing the knowledge, availability, and effectiveness of Natural Family Planning (NFP). Papers and discussion from 4 of the 13 conference sessions are included in this volume, along with abstracts of the remaining papers presented. The nine additional sessions will be published by Georgetown University in the spring of 1992.

NFP is an important topic for the fields of reproductive health and population. It is generally accepted that new hormonal or surgical methods of contraception will not be available in the next decade' and that the need for nonhormonal, noninvasive methods is well documented.2 Data from recent Demographic and Health Surveys indicate significant use of periodic abstinence—abstaining from intercourse for the purpose of avoiding pregnancy—in many countries throughout the world. However, most women who identify periodic abstinence as their family planning method have little knowledge of their fertility and thus use the method ineffectively. Many more who use no method of family planning or who would prefer to use natural methods are similarly uninformed. This leads us to ask such questions as:

- Can established NFP methods, such as the Billings ovulation method and the symptothermal method, be taught more efficiently? How effective are these methods in actual use?
- How can advances in prediction and detection of ovulation be applied to NFP? Will these advances

- make NFP easier to use? More effective? More acceptable to a wider variety of people?
- What are the outcomes of pregnancies that result from aged gametes (an issue of particular importance to NFP users, because pregnancies are most likely to occur from intercourse at the "extremes" of the fertile period)? Is the sex of the child determined by when intercourse occurs relative to ovulation?
- Given the effect of breastfeeding on fertility, how
 can an interface be created between breastfeeding
 and NFP? Can breastfeeding women use NFP?
 What role should the lactational amenorrhea
 method play in NFP? At what point postpartum
 do they need to begin to use NFP if they wish to
 avoid a pregnancy?

The current volume addresses these important questions. We believe the findings will help all of us address the fertility and reproductive health needs of women and couples in both developed and developing countries.

In addition, the conference responded to other important questions. Abstracts of these findings are contained in the current volume. The complete findings are to be published by Georgetown University in Spring 1992. It will include findings on such questions as:

- What are the behavioral issues that influence NFP use? How can abstinence during the fertile phase of the woman's menstrual cycle be dealt with in a variety of sociocultural settings?
- How have policies of funding agencies and other international organizations influenced the availability of NFP services? What steps can be taken to strengthen their support for natural methods?
- What are the best ways to provide fertility awareness information, which underlies NFP use, to special target audiences such as adolescents or low literacy women?
- How can NFP services be expanded while quality of services is maintained?
- How can various levels of health care providers be trained in NFP?

We hope our readers will find the current volume informative and thought provoking and that they also will take advantage of the additional information in the

6/0/34940

sessions to be published by Georgetown University in the Spring of 1992. We look forward to continued collaboration with our colleagues who participated in the conference and to a new dialogue with those whose interest in NFP is stimulated by the information presented here.

SESSION I. MAJOR SCIENTIFIC ISSUES IN NATURAL FAMILY PLANNING

John T. Queenan, Co-Chair Kamran S. Moghissi, Co-Chair Barbara Gross, Rapporteur

Natural family planning: Looking ahead

John T. Queenan, MD, and Kamran S. Moghissi, MD

Washington, D.C., and Detroit, Michigan

Natural family planning is used by a relatively small number of people worldwide. The Institute's goal is to increase the knowledge, availability, effectiveness, and acceptability of natural family planning. To do so, the Institute is conducting biomedical research in several areas including: (1) the development of a home test kit for cvulation prediction, (2) sperm-mucus interaction, (3) the mechanisms and fertility impact of lactational amenorrhea, and (4) outcome of pregnancies in natural family planning users. (AM J OBSTET GYNECOL 1991;165:1979-80.)

Key words: Natural family planning, ovulation prediction, sperm-mucus interaction, lactational amenorrhea, pregnancy outcome

When the Institute for International Studies in Natural Family Planning began its 5-year cooperative agreement with the Agency for International Development, numerous studies had identified the use-effectiveness of natural family planning (NFP) as 5 to 40 pregnancies per 100 women-years, roughly equivalent to the pregnancy rate for diaphragms (14%) and condoms (10%). The multicenter, multinational World Health Organization (WHO) study of the ovulation method of NFP demonstrated that for couples who used the method correctly, it was 97% effective for all sites combined. They also found that 94% of women could identify the fertile phase after a suitable training period of approximately 3 cycles.²

If a method can be so effective, why is it not more widely used? Although NFP use is relatively high among family planning users in some countries, such as Peru with 41%, the Philippines with 23%, and Haiti with 22%, its use in many other countries is far less. Considering all women, however, not just those who use a family planning method, the rate of NFP use is rarely as high as 5%.3

20007. 6/0/33246 At the outset, our mission was to increase the knowledge, availability, effectiveness, and acceptability of NFP for child spacing worldwide. In 1987, breastfeeding as a means of child spacing also became a major focus of this project. While others in this conference are addressing issues of availability, effectiveness, and acceptability, we draw your attention here to issues of knowledge, specifically the information that responsible health care providers and clients need.

Current research

As we began our work at the Institute, it seemed obvious that to convince health professionals to support an increase in the use of NFP, we needed to concentrate on knowledge, in particular, on learning more about the aspects of reproductive physiology that affect NFP. Heretofore, most research focused on mucus and temperature changes as they delineated the fertile and infertile periods. Modern research techniques and recent scientific advances could offer possible new answers to several major questions. Thus our mandate was clear:

1. It was time to develop a simple home test kit to predict ovulation early enough to avoid pregnancy. This would be extremely useful in situations in which NFP is difficult to use effectively, such as during the perimenopause or in women with irregular cycles or vaginal infections. A home test kit could be even more important as an educational tool to reinforce how the body responds to the fertility cycle. It could help adolescents

- learn fertility awareness in a positive way as they develop self-confidence about their sexuality.
- 2. It was important to investigate not only the presence and quality of mucus but also what was happening at a molecular level to prevent and/or facilitate fertilization. This is important because it could identify the parameters of sperm entry and survival.
- 3. It was clear that lactation confers some degree of infertility. However, to recommend a method of child spacing relying on lactation-based parameters required the collaboration and consensus of the experts in the field, a requirement that was met by the Bellagio Consensus Conference on Breastfeeding (August 1988).4 As we study what regulates the gonadotrophins in lactation, we learn more about what differentiates the fertile and infertile periods and can speak more confidently about the specific parameters of lactational infertility and the lactational amenorrhea method.5 There is still concern about the safety of the lactation amenorrhea method, particularly regarding the health effects on the mother of promoting exclusive breastfeeding in borderline nutritional situations.6 Research on this and other maternal safety issues must be carried out to answer valid public health questions.
- Concern also remained about the safety of NFP, particularly with regard to pregnancy outcome.

Some scientists had suggested that pregnancies resulting from aging gametes, whether preovulation or postovulation, might result in suboptimal pregnancies. As with any method of family planning, it is important that we are able to provide information and make recommendations based on clear evidence of reproductive risk. The papers in this session address these issues.

Fetal outcome among pregnancies in natural family planning acceptors: An international cohort study

Joe Leigh Simpson, MD,^a Ronald H. Gray, MD,^b John T. Queenan, MD,^c Robert T. Kambic, MSH,^d Alfredo Pérez, MD,^e Patricio Mena, MD,^f Michele Barbato, MD,^g Francisco Pardo, MD,^b Guillermo Tagliabue, MD,ⁱ Adenike Bitto,^b and Wilma Stevenson, BAⁱ

Memphis, Tennessee, Baltimore, Maryland, Washington, D.C., Santiago, Chile, Milan, Italy, Bogota, Colombia, and Lima, Peru

This international, multicenter, prospective cohort study examines the outcome of pregnancies associated with aging gametes. Comparing pregnancies conceived at or near the peak mucus phase with those occurring before or after the peak provides a means of evaluating the effect of aging gametes. The outcome criteria are (1) rates of spontaneous abortion. (2) low birth weight, and (3) congenital malformations. Preliminary analysis shows a trend toward increased spontaneous abortion with aging gametes in certain subsets (women with prior pregnancy losses) but no effect on birth weight. Too few method failures have yet been studied to make a definitive statement on congenital malformations. (AM J OBSTET GYNECOL 1991;165:1981-2.)

Key words: Natural family planning, fetal outcome, aging gametes, congenital malformations, spontaneous abortion

Fertilization involving aging gametes is associated with chromosomal abnormalities in animals, as reviewed elsewhere by our group. The phenomenon is thus plausibly said to be an inherent risk in inadvertent pregnancies occurring during the practice of natural family planning (NFP), a method based on abstinence during the fertile phase of the menstrual cycle. If an increase in chromosomal abnormalities result from aging gametes, one would expect an increase in spontaneous abortion rates, because at least half of all firsttrimester abortuses show chromosomal abnormalities. Unfortunately, methodologic shortcomings in assessing loss rates and anomaly rates in published studies of NFP users have precluded definitive statements concerning NFP safety despite the general belief that in the programmatic sense NFP does not pose undue risks. The best designed cohort study was that of the World Health

Organization; however, only pregnant women were identified, and many were lost to follow-up.²

Study design

In the current study reported here, two U.S. centers coordinate and analyze pregnancy outcome of couples who are tracked from acceptance in six recruiting centers in five countries (Chile, Peru, Colombia, United States, and Italy). When pregnancy is first recognized, the NFP chart is collected, to be assessed for likely date of conception by an independent panel of experts unaware of pregnancy outcome. Extensive intake information is gathered at the onset of pregnancy and again at 16 and 32 weeks. Prospectively following couples allows pregnancy losses to be identified in a timely fashion, minimizes "lost" cases, and allows potential confounding variables to be assessed. A systematic neonatal examination is performed, recording major and minor anomalies, birth weight, and other neonatal characteristics. Further details of our experimental design are provided elsewhere. The analysis compares pregnancy outcome in NFP user failure/planners versus NFP method failures, because theoretically only in the latter should pregnancies involving aging gametes occur. Specifically, we are assessing pregnancy outcome in relationship to the interval from estimated day of ovulation to conception date based on the times of intercourse and mucus peak. The latter has been shown to be the single most reproducible index of ovulation in NFP charts.3

user failures in our highly experienced recruiting center (1:4), a relatively large sample is necessary. This is especially true with respect to anomalies; small sample sizes or major inadequacies of previous studies. At present 766 pregnancies have been recruited from the six centers, with 706 completed and analyzed. Most subjects (90%) practiced symptothermal or mucus methods. Several independent observers (all experienced NFP providers) identified likely conception dates without knowledge of pregnancy outcome, as described earlier.³

Results

Preliminary data indicate that pregnancy loss (50/629 or 7.9%) is not increased in this NFP population (method failure, user failure, and planned pregnancies). However, a trend toward fewer pregnancy losses is observed among pregnancies conceived by intercourse ± 1 day of the mucus peak compared with those conceived by intercourse 2 or more days before the mucus peak (aging sperm) or 2 or more days after the mucus peak (aging oocytes). The trend reaches significance among women having pregnancy losses in previous pregnancies and is independent of maternal

age. Further analysis based on these and other conception intervals (e.g., day of the mucus peak and -1 as the optimal interval) will await expansion of our sample size.

Irrespective of any possible relationship between spontaneous abortion and timing of conception, the key health care issue relates to effects on liveborn infants. To this end, preliminary analyses showed that neither birth length, birth weight, nor head circumference was correlated with timing of conception. Rigorous assessment of the relationship between timing of conception and congenital anomalies in NFP will require a relatively larger sample to achieve requisite power, for which reason recruitment is still proceeding.

Natural family planning and sex selection: Fact or fiction?

Ronald H. Gray, MD

Baltimore, Maryland

Determining sex of offspring by timing of intercourse has been a subject of intense interest for the lay public and professional community. This metaanalysis of couples practicing natural family planning provides an opportunity to evaluate sex ratios in relation to the timing of conception with several parameters, including basal body temperature shift and peak mucus as markers of ovulation. Data from six studies show a statistically significant lower proportion of male births among conceptions that occur during the most fertile time of the cycle. (AM J OBSTET GYNECOL 1991;165:1982-4.)

Key words: Natural family planning, sex selection, Y-bearing sperm, X-bearing sperm

There has long been interest in the relationship between sex ratio at birth and the timing of intercourse.

Shettles¹ postulated that smaller Y-bearing sperm may have more motility in the midcycle cervical mucus and that intercourse around the time of ovulation would result in a predominance of male offspring. In 22 cases of midcycle conceptions, he reported 19 (86%) males, whereas with 19 conceptions more distant from ovulation, he observed 16 (84%) females.¹ Billings and Westmore² also reported more male infants with midcycle conceptions, and this has popularized the belief

that sex selection by timing of intercourse is feasible and successful. However, studies designed to test Shettles1 method have failed to confirm this finding.3,4 Despite this, natural family planning (NFP) programs in many countries promote natural methods to help couples select the sex of their child by timing of intercourse.

Study results

Several investigations allow an evaluation of the sex ratio associated with conceptions around time of ovulation compared with more distant conceptions. These studies are summarized in Table I. Four studies⁵⁻⁸ provide data on the day of conception relative to the mucus peak; one used basal body temperature shift,9 and one large study of Orthodox Jews from Jerusalem used menstrual cycle characteristics and days of sexual abstinence after menses to estimate probable conception day relative to ovulation.10 With these data, we estimated the percentage of male births and the relative risk of a male birth among conceptions during the most fertile time compared with conceptions at other times in the cycle. In all but one study, the proportion of male births and the relative risk of a male birth during the most fertile time were reduced, and overall, the relative risk was 0.90 (95% confidence interval 0.84 to 0.96), which is statistically significant. If the Jerusalem data are excluded and only NFP studies are considered, the relative risk is 0.86 (95% confidence interval 0.77 to 0.95). These results suggest that there is a small but statistically significant deficit of male births among conceptions during the most fertile phase of the cycle.

Table I shows the proportion of male births by estimated day of conception with data from NFP studies. The deficit of male births is associated mainly with conceptions during the 2 days before ovulation or on the estimated day of ovulation, and the excess of male births occurs among conceptions on days -3 and -4and days +2 and +3 relative to ovulation.

One possible explanation for such a deficit of male births is that high midcycle levels of gonadotrophin may favor X-bearing sperm. To test this hypotheses, James 11 examined the sex ratio after induction of ovulation in 27 studies. In this series of 2608 births, 46% were males, which is significantly lower than the expected sex ratio. In contrast, larger studies of ovulation induction with in vitro fertilization report a normal sex ratio of 51.7% male births.12,13 Thus high levels of gonadotrophin may

^{*}Most fertile days -1 or 0 from basal body temperature shift.

^{\$} Most fertile days -1 or 0 from mucus peak.

affect the sex ratio only if conception occurs in vivo, and this suggests that the hormonal milieu of the genital tract may be a determinant of the primary sex ratio.

Conclusion

In summary, the suggestion by Shettles and Billings that selection of male offspring by intercourse around the time of ovulation is possible is contradicted by scientific data. Although there is a statistically significant relative deficit of male births resulting from conceptions during the most fertile time of the cycle, this is insufficient to allow sex selection by timing of intercourse.

Human cervical mucus: Research update

David F. Katz, MD

Davis, California

Evaluation of cervical mucus is a standard for determining the fertile period in natural family planning. Cervical mucus accepts, filters, prepares, and releases sperm for successful transport to the egg and fertilization. Recent scientific advances provide answers to how the mucus regulates fertility as its physical properties change during the menstrual cycle. Transmission electron microscopy reveals small interstices between mucus macromolecules relative to a sperm head. Thus advancing sperm must push aside or cut through the microstructure. The interstices are largest in the periovulatory phase of the cycle. Small magnetic spheres, comparable with the size of a sperm head, are now being used to study the physical properties of the mucus on the scale of individual sperm. (AM J OBSTET GYNECOL 1991;165:1984-6.)

relevance to natural family planning (NFP) is their role in the modulation of sperm transport to the upper female reproductive tract. The concept of the fertile period, within which insemination can result in fertilization, is intimately linked to knowledge of cervix/mucus function. The cervix is the target organ of a sophisticated endocrine control system, one role of which is to modulate cervical mucus properties and secretion.

Thus the hormone signals are biomarkers, not just for ovulation per se, but for biologic mechanisms also responsible for fertility. The links between reproductive hormones and such mechanisms are only partially understood. The properties of cervical mucus are one of the primary links.

Function

Our direct knowledge of the properties and function of human cervical mucus derives primarily from in vitro studies. In vivo studies in ruminants and primates (both of which have a mucus-laden cervix) have suggested the validity of extrapolations to humans. Basic biologic and clinical aspects of the cervix, cervical mucus, and sperm have been addressed in a number of comprehensive reviews.1-3 We attribute four principal functions to cervical mucus in relation to sperm: (1) Sperm are admitted from the hostile vaginal environment; (2) the entering sperm are then filtered, and seminal plasma constituents are removed from their surfaces (only morphologically normal sperm are capable of proceeding through the mucus); (3) these sperm are nurtured and supported biochemically, perhaps to prepare the sperm for or to initiate capacitation (only after which the sperm can fertilize an egg); and (4) the cervical mucus is responsible for the storage of spermatozoa and their later release (this cervical reservoir function appears designed to coordinate the timing of insemination with that of ovulation).

Physicochemically, mucus is a gel, consisting of solid and liquid phases. The solid phase is a glycoprotein polymer (called mucin), whose macromolecules interact to form a network. Many aspects of how this network is created and maintained are not yet understood. For example, the existence and relative roles of molecular cross-linking and entanglement are not yet clear. The liquid phase of mucus contains soluble proteins, inorganic salts, enzymes, and other chemical constituents.

Structure

Our knowledge and ability to study mucus have benefited from improvement in and development of several experimental techniques. Table I summarizes some of the biophysical approaches that have been helpful. Our ability to perceive the topology of the cervical mucus microstructure has been facilitated by improvements in scanning electron microscopy4 and more recently transmission electron microscopy.5 These have revealed the heterogeneous, mosaic-like nature of the microstructure and its cyclic variations. The interstices between the mucus macromolecules are small compared with a sperm cell. Thus advancing sperm must push aside and/or cut through the microstructure.

Periovulatory mucus contains a more expanded microstructure with larger interstitial sizes than early pro-

Table I. New tools for studying cervical mucus and the sperm-mucus interaction

liferative or luteal-phase mucus. Indeed, initial physiochemical studies suggest that the principal determinant of cyclic changes in mucus is its water content or hydration. 6 Because of its high hydration, mucus begins to evaporate rapidly on removal from the cervix. Thus this property per se is not particularly amenable to laboratory analysis, much less so to the self-monitoring inherent in NFP. Qualitative biochemical or biophysical changes in the mucin microstructure are a more promising target for such monitoring.

Rheologic properties

The rheologic properties of whole mucus are viscoelastic and exhibit cyclic variation. In general, sperm penetration is maximal when viscoelasticity (i.e., the effective mucus viscosity and elasticity) is minimal, which tends to occur just before ovulation. However, the few careful studies of the cyclicity of such properties have demonstrated that there are significant variations both within, as well as among, normal women.7 More advanced analytic methods, which build on our improved understanding of the biology of the sperm-mucus interaction, would reduce the technical factors that contribute to such perceived variability.

A promising new physical approach for laboratory analysis is the use of microrheometry. In our laboratory, a small magnetic sphere, comparable in size with the sperm head, is forced through mucus by an electromagnet. The details of the relationship between such applied force and the movements of the particle provide information on the viscoelastic properties of the mucus. Earlier microrheometers used spheres 200 to 400 µm in diameter.7 By "titrating" the size of the sphere down to that of the sperm head, new information on the mucus properties experienced by an individual sperm can be obtained. Such analysis is now commencing in our laboratory and should provide a more incisive perspective of mucus receptivity to sperm.

It should be appreciated that the electrochemical interaction between the sperm surface and the mucus macromolecules can also contribute to the mucus' resistance to sperm.² Increases in such affinity may be responsible for the filtering of morphologically abnormal sperm by the mucus.⁸ Little is known about the details of this phenomenon, which may also be responsible for other alterations in sperm penetrability through mucus.

Penetrability

Sperm penetration into mucus is a phenomenon dependent jointly of sperm and mucus properties. "Penetrability" of mucus implies several features of the sperm-mucus interaction, including the number (or fraction) of sperm that cross the mucus interface and the rate at which such sperm subsequently migrate through the mucus interior. The distinguishing characteristics of sperm that can successfully penetrate (and escape from) mucus are not fully appreciated. Human semen specimens with more vigorous sperm have increased ability to penetrate ovulatory human mucus. Morphologically abnormal sperm (which have inferior motility when compared with morphologically normal cells¹¹) have great difficulty penetrating mucus. 8

The structure and physical properties of the mucus interface are different from those of the interior,⁵ generally offering greater resistance to sperm progression. Thus care must be taken in peforming analysis of mucus penetrability to control for the size and shape of the interface and for the quality of the semen applied to the mucus. The common configurations for such analysis are plane slide preparations or small capillary tubes, now of rectangular cross section.^{9, 12-14}

In general, the number and rate of penetration of sperm into mucus are maximal during the periovulatory period, when viscoelasticity is minimal. However, sperm can penetrate the cellular, more viscoelastic mucus that occurs before ovulation, earlier in the proliferative phase of the menstrual cycle. Preliminary data show a correlation between such precocious sperm penetrability and rising serum (or urinary) estrogen levels. Sperm penetrability begins to drop immediately after the peak in luteinizing hormone secretion.

It should be emphasized that in vitro sperm penetration into mucus does not guarantee sperm survival and escape from the mucus, both of which must occur in vivo. Understanding the sperm-mucus interaction must allow for changes in mucus properties in vivo after initial sperm entry. These considerations are particularly relevant to NFP, in which changes in mucus properties and/or the sperm-mucus interaction can contribute to the determination of the fertile interval during the menstrual cycle.

In conculsion, developments in our knowledge of mucus and sperm and in methods for their analysis can now be used to perform more integrated, sequential analysis of how mucus accepts, filters, prepares, and releases sperm for successful transport to the egg and fertilization.

Symptothermal and hormonal markers of potential fertility in climacteric women

Anna M. Flynn, MD, Patricia James, PhD, William P. Collins, DSc, and Patrick Royston, MSc

Birmingham, England

One hundred seventy-seven menstrual cycles in 36 women between 45 and 53 years of age were studied prospectively. All the women were experienced in the symptothermal method of natural family planning. The objective was to determine the symptothermal and hormonal indices of potential fertility by measuring urinary estrone glucuronide and pregnanediol glucuronide. Thirty-three percent had regular cycles consistent with potential fertility, 19% had cycles consistent with infertility, and 47% had a mixture of both types of cycle. (AM J OBSTET GYNECOL 1991;165:1987-9.)

Key words: Natural family planning, climacteric, menopause, fertility

The climacteric has been defined as a gradual transitory phase in the human female between the ages of reproductive and nonreproductive ability. The time when fertility starts to decline is difficult to determine for an individual. The mean marital fertility rate, however, is markedly reduced in women who are over 45 years old. The menopause (i.e., the last menstrual period) occurs most frequently during the fiftieth year of life. This event is a sign that potential fertility has been lost, but the time can only be determined retrospectively (usually after 1 year has elapsed). Accordingly, there is a need for reliable methods to determine the times of potential fertility in women who are over 47 years old and premenopausal.

Use of natural family planning

Natural methods of family planning depend on the detection and interpretation of clinical signs of potential fertility. The results from studies of preclimacteric women (aged 25 to 35 years) have shown that symptothermal changes (e.g., in basal body temperature and the characteristics of cervicovaginal mucus) correlate well with indices of ovarian function and the probable times of potential fertility. In addition, the results of prospective clinical trials have shown that methods of contraception based on periodic abstinence can be as

effective as most alternative procedures.^{5, 6} During the climacteric, however, the traditional signs of potential fertility are frequently erratic and difficult to interpret.⁷⁻¹³ Furthermore, new signs of diminished fertility (e.g., hot flushes, night sweats, and mastalgia) start to appear, but their significance in natural family planning has not been evaluated. Consequently, we have undertaken a prospective, comprehensive study of symptothermal and hormonal indices of potential fertility during the climacteric.

Aims

There were five principal aims: (1) to determine the within- and between-women variation in menstrual cycle length during the climacteric; (2) to determine daily changes in the urinary excretion of hormone metabolites; (3) to define criteria for potential fertility; (4) to examine temporal relationships between the times of defined changes in clinical and hormonal indices of ovarian function; and (5) to ascertain the most reliable indicators of potential fertility during the climacteric.

Plan of investigation

We planned to study 40 women (aged 45 to 54 years), who were experienced users of the symptothermal method of natural family planning, for 6 calendar months. All volunteers were asked to complete a daily record of vaginal bleeding, basal body temperature, the characteristics of the cervix and cervicovaginal mucus, and climacteric symptoms (hot flushes, night sweats, breast tenderness, and dyspareunia) that occurred during the previous 24 hours. In addition, each woman collected a daily sample of early morning urine for retrospective analysis of estrone glucuronide (EG) and pregnanediol glucuronide (PG) by time-resolved theorescence immunoassay.

Table III. Cross tabulation of menstrual cycles by class according to changes in urinary EG and PG

EG class	0	1	2	Total
0	12	2	8	22
1	7	0	4	11
2	6	8	3	17
3	$\frac{15}{40}$	<u>4</u>	$\frac{108}{123}$	<u>127</u>
Total	40	14	123	177

Preliminary results

Thirty-six women (aged 45 to 53 years; median, $45\frac{1}{2}$ years) were recruited, and 177 menstrual cycles were identified retrospectively (length, 16 to 103 days; median, $27\frac{1}{2}$ days). The number of cycles per woman ranged from two to seven.

Potential fertility

Defined changes in the daily concentrations of EG and PG were used to classify each menstrual cycle retrospectively as potentially fertile or not potentially fertile (i.e. infertile). The parameters for the algorithms¹⁴ used to identify a rise and peak in the urinary excretion of EG and a rise in PG were derived from a second analysis of the data obtained from a similar study of 73 women (aged 21 to 35 years) over 118 menstrual or conception cycles.¹⁵ The values and additional criteria

to determine potential fertility for this study are shown in Table I.

The menstrual cycles during the climacteric were classified according to the changes in EG and PG as shown in Table II. A cross tabulation of the classification is shown in Table III. Sixty-one percent (108/177) of the menstrual cycles were defined as potentially fertile on the basis of criteria for EG and PG appearing normal. The numbers of all women (and menstrual cycles) showing the characteristics consistent with potential fertility, infertility, and a mixture of cycles that produced periods of potential fertility are shown in Table IV. Of the 88 cycles from women in group 3, 45 were potentially fertile and 43 were infertile.

Comment

The results from this preliminary analysis of the data suggest that about 33% of women between the ages of 45 and 54 years experienced regular menstrual cycles that were consistent with periods of potential fertility. About 19% had menstrual cycles without signs of potential fertility, and the remainder (47%) had a mixture of both types of cycle. This method of classification is likely to overestimate the number of potentially fertile cycles (because ovulation need not necessarily occur even in the presence of normal hormonal changes). This probability means that we will error on the side of caution when the results are used to develop a strategy for contraceptive practice.

The data are also consistent with epidemiologic ev-

	Potential	lly fertile	Infe	rtile	potentia	ture lly fertile ıfertile	To	ptal

Table IV. Number of all women (and menstrual cycles) classified according to potential fertility

idence of a gradual transition over time from regular cycles of potential fertility to total infertility. An analysis of the data from women with potentially fertile cycles has shown that the cycle length and clinical indicators have similar usefulness for predicting the start and finish of a defined fertile period to those observed in younger women.¹⁴ Conversely, a first analysis of our data has shown that the same clinical indicators may not always reflect the underlying physiology in women with infertile cycles (data not shown). These aspects will be a smaller proportion of the subjects of a subsequent publication. Consequently, it is apparent that new markers are required to predict those cycles in which a period of potential fertility will occur from those in which it will not. A simple dipstick for a urinary metabolite that provided this information would greatly reduce the false-positive rate of subsequent tests to define precisely the time of potential fertility.

Breastfeeding: A natural method for child spacing

Peter W. Howie, MD

Dundee, Scotland

Lactational amenorrhea plays an important role in child spacing. Recent research has led to a consensus regarding the status of lactational amenorrhea as a method of family planning. This is currently referred to as the lactational amenorrhea method. Research priorities were to field test the lactational amenorrhea method and define the factors that influence lactational amenorrhea and the interface between the lactational amenorrhea method and other family planning methods. (AM J OBSTET GYNECOL 1991; 165:1990-1.)

Key words: Lactational amenorrhea method, child spacing, breastfeeding, postpartum contraception, lactational amenorrhea

Areas of agreement

Although it has been known for a long time that breastfeeding causes a variable period of amenorrhea, it is only during the past 10 years that scientific attention has been focused on its role in fertility regulation.\(^1\) Progress in this area of research has led to general agreement in four main areas.\(^2\) First, it is now clear that breastfeeding is associated with a reduction in fertility, which is closely related to the duration of amenorrhea.\(^3\) This has been shown particularly in those populations in whom prolonged breastfeeding, in the absence of artificial contraception or postpartum sexual abstinence, causes substantial durations of infertility that may last for as long as 2 years or longer.\(^4\)

Second, detailed endocrine studies have shown that inhibition of ovulation through gonadotrophin suppression is a key factor in lactational amenorrhea.⁵ After the resumption of menstruation, breastfeeding may reduce fertility to some extent, but the effect is much less marked compared with the period of lactational amenorrhea.⁶

The third factor of importance is that the maintenance of lactational amenorrhea is suckling dependency.⁷ Those mothers who suckle frequently for long periods and maintain breastfeeding at night experience longer periods of lactational amenorrhea than those who reduce suckling frequency or duration at an early stage, sometimes in response to the rapid introduction of supplementary feeds.⁸ Because breastfeeding practices differ widely across cultures, it has proved impossible to define a minimum level of suckling that will

6/0/34941

guarantee the maintenance of lactational amenorrhea and that could be applied universally. Nevertheless, many studies have shown that more intensive suckling is associated with longer periods of lactational amenorrhea.²

The fourth point on which there is general agreement is that lactational amenorrhea makes an important contribution to overall fertility as expressed by completed family size, particularly in those countries in which the use of artificial contraception is low.9 At an individual level, lactational amenorrhea makes an important contribution to the effective spacing of births, which, in turn, has important advantages for both infant mortality and morbidity. All these factors strongly add to the justification for making the protection and promotion of breastfeeding an important international health objective.

Future research issues

Despite the progess made during the past 10 years, many important questions about the use of breastfeeding for child spacing remain unanswered. The Institute and others have initiated several studies in this area. The Bellagio Consensus statement² notes that during the first 6 months, postpartum mothers who fully or nearly fully breastfeed and maintain lactational amenorrhea can expect a pregnancy rate of less than 2%. An algorithm incorporating these three criteria (the infant is <6 months of age, the mother is amenorrheic, and full or really-full breastfeeding is being practiced) has been developed by Dr. Miriam Labbok and serves as the basis for the lactational amenorrhea method (LAM).10 It is important that the robustness of these guidelines be tested in field studies within a number of different cultural settings so that they can command the confidence of health workers advising postpartum mothers about contraception.

A second priority is to define more fully those factors that may influence the duration of lactational amenorrhea. Possible factors that may be of importance include maternal nutrition, racial differences, individual biologic variation, and other factors such as maternal illness. A multicenter study of 550 subjects in each of seven centers has been funded by the World Health Organization and supported by the Institute for International Studies in Natural Family Planning to define those confounding factors that are of principal importance in determining the duration of lactational amenorrhea.

The third area of importance for future study is the interface between LAM and alternative methods of family planning. Towards the end of lactational amenorrhea, fertile signs may be particularly difficult to interpret, and very little is known about what factors influence mothers and health professionals to determine when alternative family planning methods are required. The strategy of introducing artificial contraception at an early stage during the postpartum period will not in many cases be either necessary or an effective use of scarce resources.

The final priority for the future is to disseminate accurate and effective information about LAM that can be easily interpreted by health workers and understood by breastfeeding mothers. A major need exists for effective operational research to determine the best ways whereby the substantial advantages of LAM can be used to best effect in both developing and developed country

settings. However, it is clear that by ensuring effective birth spacing, breastfeeding and LAM will continue to be an important factor in both maternal and child health, particularly in developing countries.

Conclusion

John T. Queenan, MD, and Kamran S. Moghissi, MD Washington, D.C., and Detroit, Michigan

Much biomedical research has been accomplished during these 5 years of our cooperative agreement, and considerable work is still in progress. As we look at the use of natural forms of fertility regulation for the future, definitive areas that need additional scientific study include the following:

- 1. Develop a simple home test kit that could predict ovulation 4 to 5 days in advance.
- Determine whether aging gametes, as seen in natural family planning (NFP) "method failures," have any bearing on incidence of spontaneous abortion, low birth weight, or congenital malformations.
- 3. Determine a definitive answer on whether aging gametes are related to sex selection.
- 4. Study mechanisms of mucus receptivities and hostility to sperm in promoting and preventing pregnancy to explore areas for modification of or improvement in periodic abstinence.
- Study the perimenopause and other special circumstances to elucidate how women in these reproductive states can use periodic abstinence effectively.
- 6. Study the lactational amenorrhea method (LAM) in a variety of clinical settings to test the assertion of 98% effectiveness for preventing pregnancies for the first 6 postpartum months.
- 7. Study the health sequelae of exclusive breast-feeding.

From the Institute for International Studies in NFP, Department of Obstetrics and Gynecology, and the Department of Obstetrics and Gynecology, Wayne State University/Hutzel Hospital, Division of Reproductive Endocrinology and Infertility. 6/0/33244

- 8. Study the use-effectiveness of LAM beyond 6 months, beyond supplements to, and beyond menses return.
- 9. Study the neuroendocrinology of lactation with the goal of enhancing the infertile period.

Such studies require considerable financial support. The basic science studies often are funded by the National Institutes of Health or private research foundations. The use-effectiveness and some of the basic science studies have been funded by the Agency for International Development and the World Health Organization. A need still exists for additional study, and therefore considerably more funding. We hope that the information presented at this meeting will challenge and inspire a broad spectrum of organizations to support research in natural fertility regulation (NFP and LAM)—the international donor organizations, public and private research agencies and foundations, and religious groups whose beliefs proscribe the use of any methods other than the natural methods.

As each new family planning method is developed, it is only a matter of time until major and minor drawbacks are recognized. NFP is no exception. Certainly it has its drawbacks, including the requirements for self-observation and the need to adjust behavior to meet fertility intentions—in short, the drawbacks of any user-dependent family planning method. Because NFP uses no chemical or device, it will always be attractive to certain groups of women in their reproductive years. Because the cost of education and maintenance is negligible, NFP has a very practical importance from a public health standpoint. If couples are exposed to accurate data on this method, it will become an attractive alternative for many.

SESSION II. OVULATION PREDICTION: PRESENT DEVELOPMENTS AND FUTURE NEEDS

Michael J. Zinaman, Chair John T. France, Co-Chair Sanford Markham, Rapporteur

Overview and issues in ovulation prediction

Michael J. Zinaman, MD, and John France, DScb

Washington, D.C., and Auckland, New Zealand

Recent advances in our understanding of the physiology of reproduction have led to the ready availability of tests that allow women to self-monitor their fertility potential. Home pregnancy tests were the first to be marketed to the general public. Shortly thereafter, urinary luteinizing hormone tests also became available. In the privacy of her own home, a woman can now comfortably monitor for impending ovulation; by the time of her expected menstrual period, she can identify whether or not she is pregnant. However, there remains a great need for the development of further tests that women can use to identify the days of her cycle on which sexual intercourse is likely to result in pregnancy. (AM J OBSTET GYNECOL 1991;165:1993.)

Key words: Reproductive physiology, self-monitoring, fertility potential

Advances in research have allowed us to show that sperm can survive in human cervical mucus and maintain their fertility potential for up to 5 days or perhaps even more. Much of their survival appears to be dependent on the presence and characteristics of the mucus itself. At the same time, we have recognized that the fertile period ends perhaps as early as 12 hours

6/0/33243

after ovulation. It has been a role of the Biomedical Division in the Institute to support research to develop simple tests for the self-monitoring of fertility potential including, in particular, the identification of both the onset and end of the fertile period. The use of such tests will allow couples to enhance their fertility awareness and increase their knowledge of their reproductive status.

The following papers present some of the recent progress made by both industry and academic researchers toward producing simple test systems that might be used in the home for defining the fertile period. It is apparent that while much work has been done, significantly more effort is needed to make these tests a reality.

The evolution of reference methods to monitor ovulation

William P. Collins, DSc

Denmark Hill, London

Reference methods to predict or detect ovulation have evolved substantially during the past few decades. The potential use and limitations of such methods are reviewed. The use of transvaginal ultrasonography with color flow mapping to monitor periovulatory changes in the intrafollicular morphology and blood flow is described. (AM J OBSTET GYNECOL 1991;165:1994-6.)

Key words: Ovulation prediction and detection, vaginal ultrasonography, oocyte, fertile period

Ovulation is the release of one or more oocytes from the ovarian follicle. The event is preceded and followed by a complex series of functional and morphologic changes within the ovary and other organs of the female reproductive tract. The only definitive evidence that ovulation has occurred is the identification of an ovum or preembryo in an extraovarian location or by the detection of a pregnancy. Neither of these endpoints, however, can be used to evaluate reference methods for the prediction or detection of ovulation. Inevitably, there will be oocytes that are released but not found before or after fertilization or do not result in a pregnancy. This limitation invalidates the calculation of the positive and negative predictive values for any method. Nevertheless, more practical reference methods have been developed to monitor the presumed time of ovulation with the aim of helping women achieve or avoid a pregnancy.

Evolution of reference methods

The principal methods that are evolving are based on the following: (1) calendar calculations^{1, 2}; (2) a defined rise in basal body temperature³; (3) the presence and type of cervical mucus⁴; (4) defined changes in the concentration of circulating hormones⁵; (5) the immunoassay of urinary steroid glucuronides and luteinizing hormone⁶; (6) changes in ovarian morphology^{7, 8}; and (7) changes in intrafollicular blood flow.^{9, 16}

Reference methods are often modified for self-use. An improved algorithm has been developed to determine the day of shift in basal body temperature, 11 and an electronic thermometer has been manufactured and evaluated. 12 A special syringe has been produced to sample and measure the volume of cervicovaginal fluid, 13 and a simple visual test has been devised to determine the activity of the peroxidases. 14 A major

study organized by the World Health Organization⁵ involved the use of a histologic endpoint to relate defined changes in the concentrations of circulating hormones to the time of ovulation. The results are summarized in Table I.

Immunoassays for urinary estrone glucuronide (a metabolite of plasma estradiol) and urinary pregnanediol-3α-glucuronide (a metabolite of plasma progesterone) have been simplified for self-use in the form of immunotubes, ¹⁵ and urinary luteinizing hormone can be measured on an immunostick. Transabdominal ultrasonography has also been used to study the time intervals between defined changes in the concentration of plasma hormones and the time of follicular rupture (ovulation). ¹⁶ The results are summarized in Table II.

Ovulation monitoring 1995

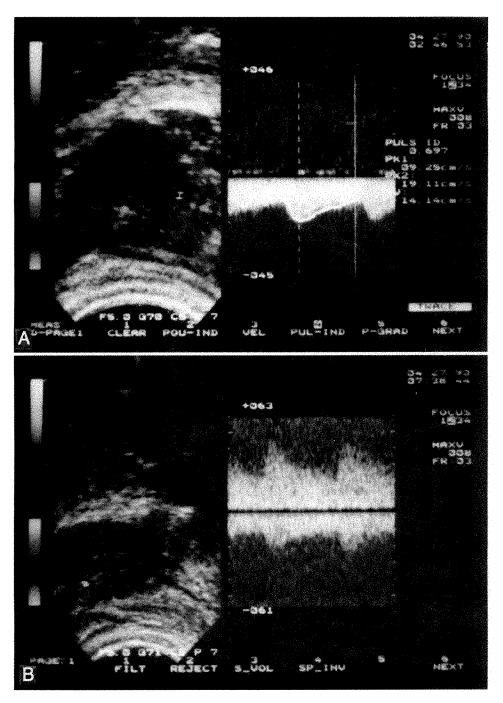

Fig. 1. A, A preovulatory follicle (at the time of the plasma luteinizing hormone peak) showing blood thaw velocity waveforms from the inner wall. B, Postrupture showing increased velocity and fuzzy waveforms. (Photograph courtesy of Dr. T. H. Bourne.)

A structure resembling the detached cumulus and oocyte is often seen before the follicle has started to rupture. More recently, transvaginal ultrasonography with color flow mapping is being used to study changes in intrafollicular morphology and blood flow during the periovulatory period. 9, 10 Blood flow velocity waveforms are observed clearly at the time of the rise in luteinizing hormone, and blood vessels are visible in the inner layer of the follicle (the granulosa layer) at the time of the luteinizing hormone peak. Concur-

rently, the wall of the follicle becomes less clear, crenated, thicker, and more echogenic. The peak systolic blood velocity frequency envelope is irregular (fuzzy) at this time (possibly indicating the presence of broken blood vessels), but becomes smoother as the process of ovulation develops. Accordingly, the visualization of blood vessels within the inner layer of the follicle and the presence of a detached oocyte and cumulus are most indicative of impending ovulation (Fig. 1), and the presence of fuzzy waveforms with high peak blood

velocity and a reduction in follicular size are consistent with the occurrence of the event.

Performance of current markers

The four main requirements of current practical markers are as follows: (1) to ascertain whether ovulation is likely to have occurred; (2) to identify the day on which the oocyte was released, for the retrospective dating of events during the ovarian cycle; (3) the immediate prediction of ovulation, to aid the treatment of subfertile couples; and (4) to identify the probable limits of the fertile period, which may be defined as the time from the fourth day before ovulation to the second day after the ovum has been released. Achievement of the last aim would be of value to couples who wish to practice family planning by periodic abstinence or the restricted use of barrier methods.

The following criteria should be considered before the performance of current markers can be assessed: (1) the type of test (including the aspect of the reproductive process being monitored); (2) the purpose of the test (i.e., the avoidance or achievement of pregnancy); (3) the age and menstrual status of the user (e.g., postpuberty, postpartum, or perimenopause); (4) the endpoints for evaluation (comparison with other tests, or pregnancy rates); and (5) the number of method or user failures.

Prospective, randomized trials are required to evaluate the clinical usefulness of each test for a specific application. The retrospective analysis of data suggests that the failure rates of methods could be low when used by motivated women of reproductive age (with regular menstrual cycles), who wish to avoid a pregnancy. Information is being collected on the potential usefulness of all tests in fully lactating women and in others approaching the menopause. At these times there are undoubtedly many false-positive and falsenegative signals of impending potential fertility. Similarly, there will be false-negative signals when the data are used by subfertile women hoping to achieve a pregnancy.17, 18 Possible signs and reasons for anovulation are being investigated, with the aim of incorporating other indices into the diagnostic procedures. A combination of tests will undoubtedly provide the best estimate of impending ovulation and potential fertility.

Idiometric assay, the third way: A noncompetitive immunoassay for small molecules

Geoff Barnard, PhD,^a Huriye Karsiliyan, PhD,^b and Fortune Kohen, PhD^c

London, United Kingdom, Istanbul, Turkey, and Rehovot, Israel

A novel, noncompetitive immunoassay applicable to the measurement of small molecules including ovarian steroids is described. Using monoclonal antibodies with the ability to recognize both β -typic and α -typic binding sites, a new simplified, sensitive, and specific immunoassay system has been developed. The initial work of this development is presented, along with preliminary results for a novel immunoassay for estradiol. (AM J OBSTET GYNECOL 1991;165:1997-2000.)

Key words: Ovarian steroids, noncompetitive immunoassay, monoclonal antibodies, estradiol

The pioneers of competitive radioimmunoassay were Yalow and Berson, who introduced a method for the measurement of insulin in 1960. Concurrently, Ekins introduced the terms "limited reagent method" and "saturation analysis" to indicate that the concentration of the binding protein was insufficient to bind all the analyte. More recently, however, he has discussed some of the limitations of competitive immunoassay, which include: (1) limited sensitivity and working range, (2) slow-reaction kinetics, (3) increased imprecision, and (4) the development of a negative endpoint (i.e., an inverse relationship between signal and analyte concentration).³

In 1968 Miles and Hales⁴ introduced a noncompetitive immunoassay that they termed immunoradiometric assay, which used isotopically labeled specific antibodies. Based on this principle, two-site, noncompetitive immunometric assays have largely replaced the earlier competitive methods for the measurement of large multiepitope analytes (e.g., protein hormones) in biologic fluids. The advantages of these excess reagent assays are greater sensitivity, precision, and working range of analyte.⁵ The major disadvantage, however, is their unsuitability for the measurement of small molecules.

Ekins⁶ has suggested that the fundamental difference between competitive and noncompetitive procedures is based solely on the detection of antibody occupancy. Accordingly, we have devised a way to detect antibody occupancy (i.e., a noncompetitive method) using two

antiidiotypes with different epitope specificity. This procedure is outlined in Fig. 1.

The term "idiotype" was originally proposed by Oudin and Michel⁷ to designate antigenic determinants unique to a small set of antibody molecules. More recently, Jerne et al.⁸ have classified antiidiotypic reagents according to the location of the idiotype recognized. Two main types of antiidiotype have been distinguished

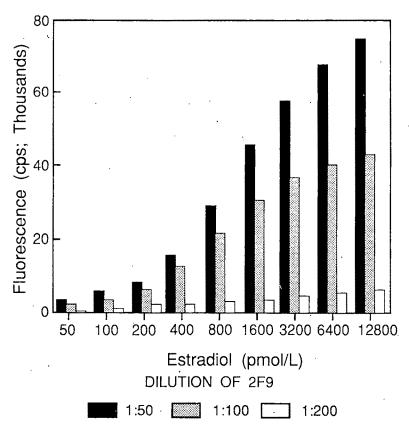

Fig. 2. Calibration curves at various dilutions of capture antibody (clone $2F_9$). Stage 1: 20 μ l of standard or sample in duplicate to the antiestradiol immunoglobulin G (clone $2F_9$)-coated microtiter wells containing 100 μ l assay buffer. Incubate and wash. Stage 2: 100 μ l β -type (clone $14H_{10}$) blocks unoccupied sites. Incubate. Stage 3: 100 μ l europium-labeled alpha-type (clone $1D_7$) addition. Incubate, wash, and fluorescence detection of occupied sites.

and these have been termed Ab2 α (α -type) and Ab2 β (β -type). By definition, β -types compete with the analyte for an epitope at the binding site (paratope). In contrast, the α -type recognizes a framework epitope and is not sensitive to the presence of the analyte at the binding site. In particular, the subset of α -types selected for the development of idiometric assay will not bind to the β -type/primary antibody complex because of steric hindrance resulting from epitope proximity.

To generate the antiidiotypic reagents, we immunized 2-month old female CD₂ mice with purified antiestradiol immunoglobulin G (clone 2F₉) in Freund's adjuvant according to a procedure previously described.⁹ After 6 months of immunization, the mouse showing the highest serum titer of antibodies recognizing europium-labeled antiestradiol immunoglobulin G was killed, and the immune spleen cells were fused in the presence of polyethylene glycol by the hybridoma technique of Kohler and Milstein.¹⁰

The initial screening procedure involved the binding of suspected immunoglobulin G from the culture supernatants of growing hybridomas to antimouse immunoglobulin G immobilized to the walls of polystyrene microtiter wells. After blocking the excess antimouse sites with nonspecific mouse immunoglobulin G, europium-labeled antiestradiol was added. Immobilized immunoglobulin G that bound the labeled reagent was indicative of a positive clone.

The second screening strategy involved the immobilization of the immunoglobulin G from the positive hybridomas. After blocking, we added europium-labeled antiestradiol that had been previously incubated in the presence and absence of an excess of estradiol (1 μ g/ml). Immobilized immunoglobulin Gs that failed to bind the europium-labeled antiestradiol in the presence of the analyte were classified as β -type antibodies.

The principle of the third screening assay is based on two-site epitope analysis similar to a procedure described elsewhere. The method involved the binding of the immunoglobulin G from the hybridomas that gave positive results in the second screening assay to the antimouse immunoglobulin G plates. After blocking, we added europium-labeled antiestradiol that had previously incubated in the presence and absence of

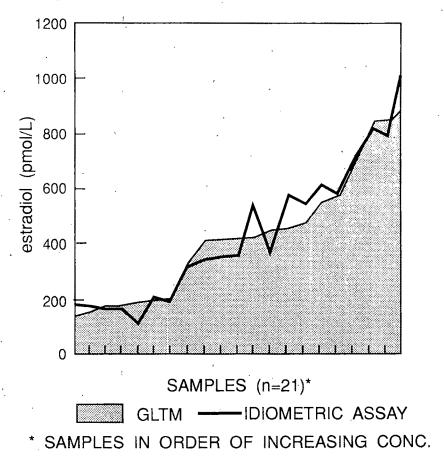

Fig. 3. Measurement of estradiol in serum. GLTM, Group laboratory trimmed means.

culture supernatants from hybridomas secreting strong β -types. Immobilized immunoglobulin G that failed to bind the europium-labeled antiestradiol in the presence of β -type was classified as an α -type.

Thirty-seven hybridomas secreting antibodies against antiestradiol (2F9) were obtained from the fusion experiment. Of these, eight demonstrated strong β -typic activity, three demonstrated weak β -typic activity, and four demonstrated α -typic activity. Appropriate clones of each class were selected and propagated as ascites in mice. The immunoglobulin Gs were purified, and the α -type was labeled with europium. 12

Using these reagents, we have successfully developed a noncompetitive, excess reagent assay system for the measurement of small molecules. This is illustrated for estradiol by the idiometric calibration curves shown in Fig. 2. In addition, we have measured the concentrations of estradiol in 21 quality control samples by idiometric assay and have compared the values with the group laboratory trimmed means. The results are shown in Fig. 3.

Currently, we are producing reagents for simple idiometric assays for the measurement of serum and salivary progesterone and urinary pregnanediol- 3α -gluc-

uronide and estrone-3-glucuronide. Furthermore, we are investigating the suitability of this approach for the measurement of peptides (e.g., buserilin) and proteins (e.g., human growth hormone).

Home tests to monitor fertility

Keith May, PhD

Bedford, England

Industry has been intimately involved in the development of products used in the monitoring of fertility at home. The perspective of industry and the development of such tests including their rationale are presented. The methods taken by industry to utilize current technology in the development of reliable, rapid, one-step tests for urinary human chorionic gonadotropin and luteinizing hormone and the subsequent expansion into other areas are covered. (AM J OBSTET GYNECOL 1991;165:2000-2.)

Key words: Fertility monitoring, home tests, monoclonal antibodies, enzyme-linked immunoassay

The concept of home/bedside testing is by no means new, and several references to this can be found dating back to the last century and even earlier. However, the gap between concept and reality can only be bridged by the advent of technology that is capable of being adapted to meet the needs of the consumer. The area of home diagnostics is currently limited to a small range of tests and is dominated today by two product categories: blood glucose monitoring and home pregnancy testing. Providing the technology that allows these tests to be routinely performed at home is a relatively recent phenomenon. The past 5 years have seen these products move even closer to the consumer's ideal as a result of a recent technologic advance.

The evolution of home tests for fertility monitoring

Pregnancy tests were the first immunoassays to enter the over-the-counter market in the mid 1970s. In the early 1980s, most of the competing products were still based on red cell or latex agglutination. The tests were not reliable for most consumers, because they were difficult to use and interpret and were basically repackaged laboratory tests. The user was presented with a miniature chemistry set containing test tubes, reagents, droppers, and urine collectors. In 1984 market research showed that people were looking for a new test that was:

- Rapid (less than 30 minutes)
- Sensitive (results as early as the first day of the missed period)
- Easy to use
- Easy to read
- Hygienic (avoided the need to collect and dispense a sample)

The development of monoclonal antibodies in 1975 by Kohler and Milstein' and its subsequent adoption by commercial companies allowed for the first time the repeatable production of specific, high-affinity antibodies in gram amounts. This advance allowed the use of high levels of antibody and led to considerable enhancements in speed and sensitivity in diagnostic tests. The coupling together of monoclonal antibodies with dipstick enzyme immunoassay technology gave further improvements in ease of use and ease of reading the result. The first of these color end point tests was the Monoclonal Antibodies Inc. Pregnastick and saw the time to complete the test reduced to 30 minutes. A further evolution of this base technology was seen by the emergence of Clearblue, which also included a unique and patented sampling device that addressed for the first time the collection of a sample (May 1988).2 All solutions were dispensed ready to use in the base unit, removing the requirement for droppers and accurate dispensing of liquids. A measure of how far this moved toward answering the needs of the consumer was seen from the success of this product in the market.

The trend in technology development in the mid 1980s was, however, still toward faster and easier testing procedures. The quest for speed led many companies to investigate membranes as alternative solid phases to coated tubes or dipsticks. Indeed, some membranebased enzyme immunoassay products started to appear in the processional market in 1986 from Abbott and Hybritech. The Hybritech Icon reduced the time to complete a test to 5 minutes. The speed enhancement was largely achieved through the presence of high levels of antibody per unit surface area of membrane and a high surface area to volume ratio within the membrane. This leads to very short diffusional distances and pseudo first-order reactions.3 The tests were still multistep and used liquid reagents that had to be added with droppers. In addition, no attention was paid to sample addition and hence were unable to meet the criteria for an ideal test proposed by consumers.

Another technology that appeared to offer the potential for widespread application was enzyme immunochromatography.4 This technique, however, appears to have limitations on sensitivity and still required liquid reagents.

Moreover, while some of these technologies moved a little closer, in 1986 there was still a gap between these concepts and consumers' ideal product. The target defined by consumers at this stage was a test that was rapid: less than 5 minutes, required no manipulation by the user, maintained the sample collection and hygienic handling of Clearblue, and provided a clear, easy to read result. To achieve this, it was necessary to replace the enzyme labels with direct labels and to make the addition of sample bring together the reactants. The first pregnancy test to reduce the manipulations, including sample collection, to one step was Clearblue One Step, which was introduced in June 1988.

The product is genuinely a one-step pregnancy test-all the user has to do is to hold the absorbant sampler in the first morning urine stream, replace the cap on the device, and wait for 3 minutes.

Clearblue One Step utilizes monoclonal antibodies in a novel, rapid assay technology and was developed and patented by Unipath. It is the only truly one-step pregnancy test and also includes a unique, built-in control that shows when the test is complete (removing the need for timing) and that the test has been carried out correctly.

The essential features of the test are an absorbent wick that is held in contact with a porous membrane material. The membrane has three separate zones of antibody in it. These zones of antibody are deposited in such a way that the first is capable of being mobilized by the sample and the other two are immobilized. When the sampler wick is saturated with urine, this passes along the membrane material until it reaches the mobile zone of reagent. The mobile reagent consists of colored latex particles sensitized with monoclonal antibody to the α-subunit of human chorionic gonadotropin (hCG). The urine picks up the colored latex and carries it to the second zone located directly below the large window. The second zone is composed of monoclonal antibody to the \beta-subunit of the hCG immobilized in the membrane. If the urine contains hCG, the hCG will react with the anti-α hCG on the latex and will allow this to be trapped by the anti-β hCG zone, causing the formation of a blue line in the large window.

The latex and urine continue to move along the strip by chromatography and come into contact with the third zone (below the small window). The third zone consists of an antimouse immunoglobulin antibody that is immobilized in the membrane. Excess or unreacted latex passing the first zone will be trapped, leading to the appearance of a blue line in the small window every time whether hCG is present or not.

Recent advances

The technology has been extended to produce rapid one-step tests for hCG, streptococcus A, and Chlamydia under the tradename Clearview. The Chlamydia test is particularly worth mentioning, because it allows relatively unskilled users to detect Chlamydia in under 30 minutes compared with the traditional culture detection methods that take 3 to 5 days. The test provides

sensitive and reliable detection of *Chlamydia* in endocervical swabs.^{5, 6}

All these tests are qualitative yes/no tests in which detection of the presence or absence of the analyte is sufficient. The extension of the technology into semi-quantitative testing is illustrated by Clearplan One Step, which allows the user to determine when levels of luteinizing hormone (LH) have reached the preovulatory surge levels.

In the presence of basal levels of LH, the control line is much darker than the test line. As the LH level increases, the intensity of the test line increases, so that when the preovulatory surge occurs (i.e., levels of 30 mIU/ml of LH or greater), the test line is of similar intensity or darker than the control line. When used by the women at home the surge can easily be detected.

The use of simple reflectance reading instrumentation provides the potential for quantitative measurements of analyses. We anticipate that many of the advances that have been made during the development of other home test kits can be expediently applied to kits for monitoring fertility.

A prototype for ovulation detection: Pros and cons

Bill L. Lasley, PhD, Susan E. Shideler, PhD, and Coralie J. Munro, BSc Davis, California

A noninstrumented enzyme immunoassay for urinary estrone conjugates was adapted from an instrumented microtiter plate enzyme immunoassay assay. The end point of the assay was a color change from green to clear, which was visible to the unaided eye. The visible color change was adjusted to allow 80 ng/ml estrone conjugates (on the basis of a sample size of $6.5~\mu l$ urine) to be distinguished from an infinite dilution without instrumentation. The evaluation of human urine collected from ovulatory ovarian cycles demonstrated that early follicular phase concentrations ($35.9~\pm~6.8$ to $79.4~\pm~14.7$ ng/ml, n=10) produced a dark-green color, whereas late follicular phase concentrations ($162.9~\pm~20.1$ ng/ml, n=10) produced no color. Daily urine samples throughout 10 ovulatory ovarian cycles produced parallel profiles when compared to measurements of estradiol in paired blood samples. Complete analysis of the data indicated that ovarian follicular dynamics can be accurately monitored through the noninstrumented analysis of daily estrone conjugates in urine samples. (AM J OBSTET GYNECOL 1991;165:2003-7.)

The events associated with ovarian follicular growth and development traditionally have been characterized by the measurement of serum or plasma estradiol. More recently, radioimmunoassay (RIA) measurements of urinary metabolites have been shown to be practical replacements for measurements of blood concentrations of estradiol in human¹⁻³ and nonhuman primates. Urinary measurements of excreted hormone concentrations have been shown to provide an accurate appraisal of estrogen dynamics during both the normal and the abnormal human menstrual cycle as well as during the periimplantation period in human beings^{3, 5} and macaque monkeys.

At the present time, efforts are being made to provide nonradiometric assay substitutes for RIA methods. Enzyme immunoassays (EIAs) have been developed for urinary steroid metabolites. Urinary analysis of ovarian function has advantages over serum analysis because subjects can collect their own samples for lengthy studies and store them by freezing without preservatives for analysis at a central site. Enzyme assay formats have advantages over RIAs in that they eliminate toxic and regulated substances, reduce monetary and labor costs of analysis, and enhance the ability to expand study designs to include the monitoring of large numbers of subjects over relatively large geographic areas. Additionally, enzyme immunoassay formats provide

the basis for the development of noninstrumented assays that can be used under nonlaboratory conditions. Such assays would allow subjects to collect and analyze their own daily urine samples and, in certain situations, detect the fertile period or anticipate ovulation.

Commercial tests are currently available for the primary metabolites of progesterone, but there are few, if any, tests for impending ovulation. Most tests, like those signaling the luteinizing hormone (LH) surge, or change in the estrogen/progesterone ratio, allow detection or confirmation of ovulation only after the fertile period has begun. Such indicators can be used for fertility enhancement, but they have little value as an aid to prospectively avoid conception.

The best indicator of the fertile period is the initiation of the preovulatory estrogen rise. This event coincides with the selection of the ovarian follicle, which will ovulate 3 to 6 days later. If the initial rise in serum estradiol is predictive of ovulation by 5 days, then it would follow that urinary metabolites also can be used for the same prediction—assuming a minimal lag time between changes in serum estradiol and urinary metabolites. We have demonstrated a preovulatory rise in both serum and urinary estrogen, but have not correlated the events in urine to those in serum using a noninstrumented assay format that could be used to document follicular development and ovulation outside of the laboratory.

The purpose of this study was to evaluate the adaptation of an instrumented EIA for estrone conjugates (EIC) to a noninstrumented EIA (NEIA). Changes in urinary EIC concentrations measured by NEIA were compared to changes in serum estradiol concentrations in paired daily blood and urine samples throughout ovulatory menstrual cycles. Comparisons were made

between estrogen concentrations in daily serum assessed by RIA and urine samples assessed by both instrumented and noninstrumented EIAs to determine the timing before ovulation of the first estrogen rise in each.

Material and methods

Subjects, samples, and previous analysis. The serum and urine samples used in this study were a subset of those described in a previous report.8 Subjects and collection of samples are described in detail in the previous report. Briefly, women between the ages of 23 and 40 years with normal menstrual cycles were recruited for the study. Daily early morning urine samples and midmorning blood samples were collected throughout one complete menstrual cycle. Samples were frozen and stored until evaluation. After evaluation, remaining urine samples were refrozen and stored for approximately 1 year. Urine samples for complete menstrual cycles of six subjects were then reanalyzed by the NEIA reported here. These ovarian cycles were previously shown to be ovulatory by the assessment of serum LH, follicle-stimulating hormone (FSH), estradiol (E2), and progesterone (Po) using commercial kits purchased from Diagnostic Products Inc. (Los Angeles, Calif.).8 In addition, cycles were analyzed for urinary ElC and progesterone (PdG) by validated laboratory methods described by Munro et al.8 Creatinine was measured by the method of Taussky (1969) to adjust for the differences in urine concentration. The day of the midcycle LH peak was used as a reference for the day of ovulation and a sustained rise of serum progesterone for 12 to 15 days was observed in all menstrual cycles studied.

Estrone conjugate noninstrumented enzyme immunoassay. The ElC NEIA is similar in format to the EIC EIA described by Czekala et al.6 and uses most of the materials reported by Munro et al.8 Three major changes were introduced to the microtiter plate EIC EIA format. High-binding star tubes (Nunc Maxisorp star tubes, Nunc Inc., Naperville, Ill.) were substituted for the microtiter plate as a solid matrix for the assay to maximize the color change during the midfollicular phase when the estrogen production of the dominant follicle signaled the beginning of the fertile period. Second, the estrone conjugate enzyme label was altered to maximize the dose response dynamic by eliminating the glucuronide moiety. This steepened the slope and provided an "all-or-none" or "binary" signal to be generated over a small change in concentration of standard or unknown. The 50% binding point of the standard curve of the ElC NEIA with estrone horseradish peroxidase as the enzyme competitor was 400 pg/tube (or

80 ng/ml on the basis of a sample size of 6.5 μ l urine) of estrone-3-glucuronide. Third, small Whatman No. 1 filter paper pads (7.5 mm diameter) were used to measure and transfer urine samples. Pads were dried completely and stored at 4° C until assayed. Several pad samples of individual urines were analyzed to test the reliability of sample volume measurement as well as the shelf life of the sample dried onto the absorbent pad. Reliability was comparable to micropipettors (6.5 \pm 0.3 μ l, n=12, coefficient of variation 1.6%); samples could be stored up to several weeks with refrigeration before analysis without loss in reactivity: one cycle was analyzed by EIC NEIA on four different occasions by use of sample pads that had been stored for more than 6 months at room temperature, with no change in results.

The EIC NEIA was performed by coating star tubes with 0.5 ml of antibody R522.8 After a minimum incubation of 18 to 24 hours, the tubes were rinsed with EIA wash. A clean filter paper pad was soaked in a urine sample for 1 to 3 minutes, blotted dry, and placed into 0.5 ml of the conjugate solution added to the precoated star tube. After a 60-minute incubation the contents of the tube was discarded, the tube was rinsed with EIA wash, and 0.5 ml of substrate was added. The visual color change was evaluated quantitatively by measuring the optical density of a 0.1 ml aliquot transferred to a microtiter plate and read on a Dynatech MR600 spectrophotometer (405 nm).

Statistics. Composite cycles were derived from mean daily hormone values of the individual subjects and were aligned according to the serum preovulatory LH/FSH peak. CUSUM analysis, as described by Royston⁹ was used to describe the pattern of urinary estrogen concentrations before ovulation. The "first rise" of serum E₂ or urinary EIC was defined as that day before the LH surge on which the mean for all cycles was greater than a reference value. The reference value was defined as "baseline plus 0.3." The "baseline," in turn, was defined as the mean of the first 6 days of each individual cycle expressed as a natural log. A significant rise was defined as that day before the LH/FSH peak on which the value exceeded the "decision interval" (0.6).

Results

When compared with serum E_2 measurements, the urinary ElC EIA values lagged behind by 0.7 day, indicating that less than 1 day was lost when the urinary dynamic of the ElC was measured in place of serum E_2 . The composite urinary ElC profile determined by EIA and the serum E_2 (concentration measured in picomoles per liter) profile determined by RIA for the same 10 cycles are shown in Fig. 1. Although composite

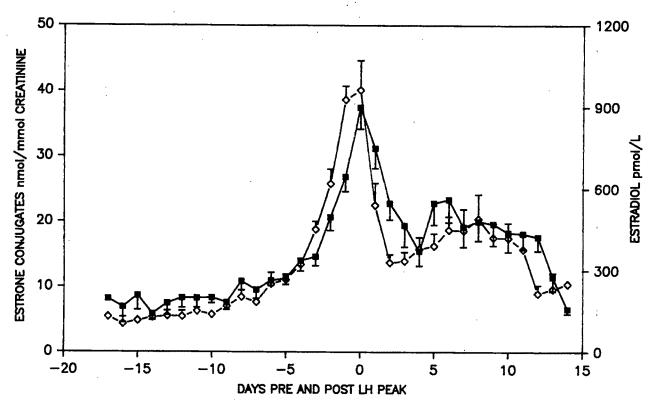

Fig. 1. Daily mean serum estradiol and urinary EIC concentrations in 10 ovulatory menstrual cycles. (From Munro CJ, Stabenfeldt GH, Cragun JR, Addiego LA, Overstreet JW, Lasley BL. Clin Chem 1991;37:838-44, with permission from Clinical Chemistry.)

peak values for both EIC and E2 occurred on day 0, four of 10 cycles had E_2 peaks on day -1 with an ElC peak on day 0, and two had E2 peaks on day 0 and EIC peaks on day +1. As previously reported, serum E₂ values showed a postovulatory nadir on day +2, and ElC values in urine showed a postovulatory nadir on day +4.3 Both serum E2 and urine ElC concentrations increased during the luteal phase, remaining at about 50% of peak values until approximately day +10 before declining to early follicular phase levels. The mean urinary ElC profile was parallel to the mean serum E2 profile (r = 0.88, p < 0.001).

Estrone conjugate evaluations of human urine by EIA indicated that EIC concentrations in the early follicular phase ranged from 35.9 ± 6.8 to 70.4 ± 14.7 ng/ml, whereas late follicular phase concentrations were as high as 162 ± 20.1 ng/ml. For the ElC NEIA to be of diagnostic use, a significant color change had to occur at the periovulatory estrogen excursion (i.e., at 70.4 ± 14.7 ng/ml urine). The high-binding star tubes showed a distinct visual color change at approximately 70 to 80 ng/ml based on an absorbent pad sample of 6.5 µl urine. Under these conditions, early follicular phase concentrations exhibited dark-green coloration, whereas late follicular phase and ovulatory concentrations were indicated by no color. In general, the dark-green color progressively lightened over two or three samples 3 to 4 days before the LH/FSH peak and was nearly colorless in all cycles on the day of the ElC peak, as determined by instrumented EIA.

When six ovarian cycles evaluated by NEIA were assessed quantitatively by transferral of both the standard curve and unknowns from the star tubes to a microtiter plate for reading the results on a spectrophotometer, a composite profile was obtained that was identical to that produced by the original EIC EIA for 10 cycles. The individual profiles of serum E2 and urinary ElC as measured by NEIA—like those measured by instrumented EIC EIA—were parallel (r = 0.88, p < 0.01).

Statistical analysis by CUSUM for the six menstrual cycles evaluated for both E2 by RIA and ElC by EIA and ElC NEIA are presented in Table I. The "first rise" is defined in CUSUM analysis as the day before the LH surge that the CUSUM becomes positive—i.e., above the reference (baseline + 0.3). Baseline is calculated as the mean of the first 6 days of each cycle and was expressed as loge, and significance is determined as the

Table I. CUSUM results for serum E₂(pg/ml), urinary E1C as measured by instrumented enzyme immunoassay and indexed by creatinine (EIA/CR), and urinary E1C as measured by the noninstrumented format and indexed by creatinine (NEIA/CR)

day before the LH surge that the CUSUM exceeds the decision interval (0.6). With these CUSUM criteria, daily serum E₂ concentrations accurately predicted the fertile period in five (86%) of the six cycles analyzed. Urinary ElC measured by microtiter plate EIA and indexed by creatinine gave similar results when the 1 day lag in excretion compared to serum E₂ secretion was considered, with a mean detection of 5.5 days, confirming that urinary ElC can be used in place of serum E₂ to predict the fertile period. Essentially the same results were obtained with the ElC NEIA as with the microtiter plate ElC EIA without indexing by creatinine.

Comment

The present study was conducted on the basis of historic data that indicate that the increase of serum E₂ concentrations accurately and consistently predict the occurrence of impending ovulation. The data presented here support that indication and demonstrate that, with early morning samples, changes in urinary estrogen excretion during the normal ovarian cycle can also be used to predict ovulation. In addition, urinary estrogen metabolites can be detected with an NEIA and that these measures also predict the ovulatory event. Although the numbers of observations are limited, a consistent rise of urinary ElC was detected as early as 6 days and as late as 2 days before the midcycle LH peak, which was comparable to the rises detected when E2 was measured in paired blood samples. In general, E₂ measurements provided an earlier and more consistent prediction of the LH surge, but the advantages of the ElC NEIA and the use of urine more than compensate for the small difference lost in predictiveness. The immediate use of this assay is to provide a selfevaluation of the major ovarian follicular events and predict ovulation several days in advance.

In five of the six cycles monitored by EIC NEIA, the preovulatory estrogen rise in urine was detected at approximately the time of the beginning of the fertile period, which is considered to be 5 days before ovulation or 4 days before the LH surge.³ It would appear therefore that this technique has the potential for prediction of ovulation by several days. This information could be used for either the timing of propitious insemination or for the anticipation of the fertile period so as to reduce the risk of pregnancy at this time.

When EIC values were combined with the measurement of urinary progesterone and luteinizing hormone metabolite measurements, the detection of the EIC rise during the follicular phase provided the ability to completely and comprehensively monitor all major ovarian events of the complete menstrual cycle. The ability to generate such information may in turn provide the basis for more detailed future studies of ovarian function in contexts in which biologic samples other than urine cannot be collected and stored for later evaluation. The EIC NEIA presented here is particularly useful when overall cycle lengths are variable or when even a general estimate of the day of ovulation cannot be made.

The inherent variations in urine concentration, which are compensated for in the laboratory by indexing each hormone value by the creatinine concentration, can, in the extreme case, contribute to false information. Whereas this is not a problem with the measurement of urinary luteinizing hormone or progesterone metabolites in which large increases of signal is exhibited over the baseline values, the relatively small baseline to peak ratio of the EIC profile is perturbed by variations in urine concentration that can be seen under normal conditions: false-positive and false-negative EIC NEIA results are to be expected when urine

osmolality is either high or low, respectively. A safeguard against such errors would be to regulate fluid intake and therefore normalize urine production during testing periods. Alternatively, urines could be tested with a simple device simultaneous to the NEIA to ensure that each urine concentration falls within a prescribed range. It seems likely that this aspect of estrogen monitoring will require the development of a noninstrumented test for urine osmolality in the near future.

Use of the Home Ovarian Monitor in pregnancy avoidance

James B. Brown, DSc, Joanne Holmes, BA, and Gillian Barker

Victoria, Australia

The application of the Home Ovarian Hormone Monitor to the avoidance of pregnancy by periodic abstinence has been explored. No woman had difficulty with the daily urine testing, and their results consistently identified the distinctive hormone pattern of the ovulatory cycle and the day of ovulation and correlated closely with the mucus symptoms. The tests gave 4 days or more warning of ovulation in 99% of cycles and allowed intercourse to be resumed 1 to 3 days after ovulation in 88%, giving a mean period of abstinence of 7 days. No pregnancy occurred from intercourse during the late safe days defined by the Monitor, but some early-day pregnancies occurred through long sperm survivals of 6 to 8 days, mostly during the return of fertility after breastfeeding. Rules for the avoidance of pregnancy, with the minimum of testing on the basis of these results, are given. (AM J OBSTET GYNECOL 1991;165:2008-11.)

Key words: Urinary estrogen, progesterone metabolites, fertile period, home test, Ovarian Monitor

The Ovarian Monitor measures estrone glucuronide (EIG) and pregnanediol glucuronide (PdG) separately by homogeneous enzyme immunoassay with final readout in a specially designed meter. The Ovarian Monitor and its validation have already been described. Its application to the home monitoring of ovarian responses during gonadotropin therapy and the close agreement between the results of home and laboratory testing have been published recently.²

This article presents the results obtained during the past 3 years in the application of the Monitor by women at home for avoidance of pregnancy.

Methods

The rules for use of the Monitor for avoiding pregnancy are shown in Table I. The ElG baseline and the first ElG rise are determined during the first cycle tested by essentially the same procedure as for establishing the rise in basal body temperature. The rise is usually quite definite. When in doubt, however, the women would abstain, but for the present assessment, the next more definite day was taken. Furthermore, particularly in long cycles, several rises may occur before the ovulatory rise takes place. In such cases, the day of the rise was the one that proceeded directly to the preovulatory ElG peak and fall, immediately followed by the PdG rise that reached the "cutoff."

The PdG cutoff was established from an earlier data bank of 104 cycles that showed that no woman who reached 6.3 µmol/24 hr after an estrogen peak and fall accompanied by a pregnanediol rise ever showed evi-

From the St. Michael Research Foundation and the Department of Obstetrics and Gynecology, University of Melbourne. dence of ovulation later in the cycle. This observation has been confirmed in the present study and has led to the confidence that is now placed in the definition of the postovulatory infertile days (late safe days) by these criteria.

The three-quarter rule (see Table I under Breast-feeding) was introduced for breastfeeding women and perimenopausal women who have a deficient luteal phase and whose PdG values never reach cutoff.

Results

The results obtained in a 3-year study involving 37 women who used the Monitor for pregnancy avoidance over a total of 661 months or 55 women-years are shown in Table II and Figs. 1 and 2. Fig. 1 shows the correlation between the day of the first ElG rise, the day of first mucus production, the day of "peak" mucus symptom, the day of the preovulatory ElG peak, and the day of the PdG cutoff in 12 women over 264 menstrual cycles up to mid-1989. Notice the close correlation between the first day of the ElG rise and the first day of mucus production; the days almost coincided in every case—the close fit of "peak" mucus with the ElG peak that occurs on the day before ovulation and the cluster of the PdG cutoff days on days 2, 3, and 4 after the ElG peak. The correlations between estrogen values and mucus observations are almost the same as those reported for laboratory measurement.3.4 The close correlation between the hormone values and the mucus symptoms the women can now observe provides them with important reassurance that both are correct.

Fig. 2 shows the more recent results produced by 33 women for 305 cycles. These included early ovulatory cycles from 12 breastfeeding women who had already been monitored for a total of 92 months during lactational amenorrhea. The emphasis in Fig. 2 is on the period of fertility as defined by the ElG rise and the

Table I. Rules regulating use of the Ovarian Monitor and the results it provides for avoiding pregnancy through periodic abstinence

General rules 1. Low E1G ("baseline"), low PdG 2. Raised E1G, low PdG	· ·		* .	,		-	Infertile Fertile
3. Raised PdG Cycling women	ć	•			,	,	Infertile

Establish early E1G baseline before resuming intercourse; use basic infertile mucus pattern (BIP) as backup
 Abstain when E1G rises above baseline and/or BIP changes

- 3. EIG rises to a peak and then falls; watch for the fall; this marks the day of ovulation and is the most fertile day of the cycle
- 4. Change to PdG measurement; watch for the PdG rise to cutoff (7 mmol/24 hr); can resume intercourse immediately; no further measurement or observation is needed in this cycle

Breastfeeding

1. Measure E1G once a week until 6 mo and twice a week between 6 and 10 mo; all days of persistently low baseline E1G values are available for intercourse; observe BIP for additional information

2. If E1G values rise, test more frequently and abstain

- a. If they rise marginally and return to baseline, intercourse can be resumed after 3 days; be careful; watch for the next rise
- b. If they rise above T 180 then fall, test for ovulation with PdG; intercourse can be resumed when PdG reaches cutoff or thirty-four cutoff if cutoff has not been reached on the third day after the E1G fall; from then on, monitor as for ovulating women

^{*}One of the pregnancies resulted through inappropriate use of the three-quarters rule.

PdG cutoff. In this series, most of the assays were performed on late afternoon 3- to 4-hour specimens of urine so that the decision to have intercourse was based on immediately preceding hormone values. In this case, the latest act of evening intercourse before the period of fertility would occur on the day before the ElG rise, and the first act of intercourse after ovulation would occur on the same evening the PdG cutoff was reached. Ovulation is assumed to occur on the day of the ElG fall after the preovulatory peak. Too long a warning provided by the ElG rise would result in unnecessary abstinence.

It must also be appreciated that ovulation is a 15-minute event at the longest and that daily monitoring cannot be more precise than 12 hours in timing this event. Fig. 2 shows that the ElG rise gave a minimum of 3 days' warning of ovulation and 4 to 8 days' warning in the majority. This would seem to be an excellent result when most workers consider that 3 days' warning would be adequate. In 28 cycles, no early safe days were provided. In the great majority of cycles, the PdG cutoff occurred on days 1, 2, or 3 after ovulation, but in six it occurred on the presumed day of ovulation without conception. One woman contributed three of these cycles and was recording intercourse on that day.

There are several explanations for these findings.

The most likely is that day 0, as defined by the ElG drop, was in error by a day because of the daily sampling and that the PdG cutoff provided the more accurate information on ovulation. Furthermore, the high PdG values reflect high progesterone values that themselves may be contraceptive, like the progestogen in combination oral contraceptive.

The important points to be noted are (1) the PdG cutoff and protection from pregnancy occur frequently on the day after ovulation, (2) the results emphasize the reliability of the test that distinguishes the day of maximum fertility in a cycle from the next day of total infertility, and (3) the median length of abstinence required by the Monitor was 7 days.

Comment

This series of 661 months of observation in pregnancy avoidance resulted in four pregnancies, representing a pregnancy rate of 8 per 100 women-years (see Table II). The exact sequence of events that occurred in the conceptual cycles were clearly revealed by the Monitor results, and they provided much of the important information summarized in the conclusions.

The women in the study were not selected by socioeconomic status, none was deemed unsuitable for training, and none had difficulty in performing the test.

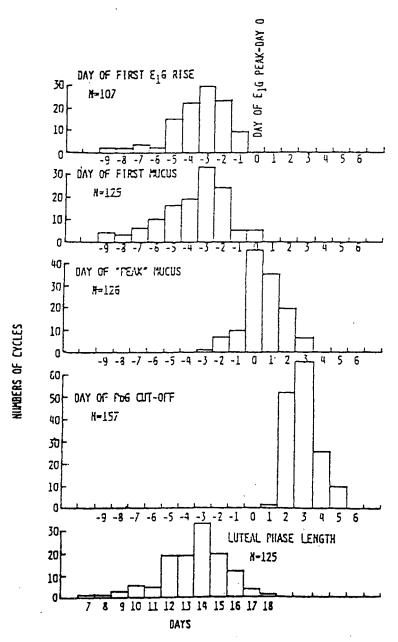

Fig. 1. Correlation between the day of the first ElG rise, the day of onset of fertile mucus symptoms, the day of the "peak" mucus symptom, and the day of the PdG cutoff in 12 women over 264 menstrual cycles.

The majority were more than 30 years of age with three or more children and had therefore completed their families and wanted a secure method to avoid pregnancy. Their views on the test and its use were sought by means of a questionnaire. Most considered the test a nuisance and they would like the work load to be reduced, although this was not a sufficient reason for stopping because of the sense of security it provided.

Most women combined the hormone values with the mucus symptoms to define days of potential fertility. Sixty-two percent were having sexual intercourse during the early safe days. All were using the late safe days; 21 used late safe days immediately after the PdG cutoff was reached and 13 added several days according to

the mucus rules for additional safety. Some women had difficulty remembering the times of urination, and some measurements were lost because it was too late to collect another specimen.

Although most subjects preferred doing the tests during evenings, social activity could create difficulties, particularly on crucial days when the measurement could not be left until the next day. Most of these objections have been accommodated by teaching the women to organize the testing to fit in better with their daily activities.

Home and lay-center usage of the Monitor throughout Australia added to the present series now amounts to 300 women-years of experience. On the basis of feed-

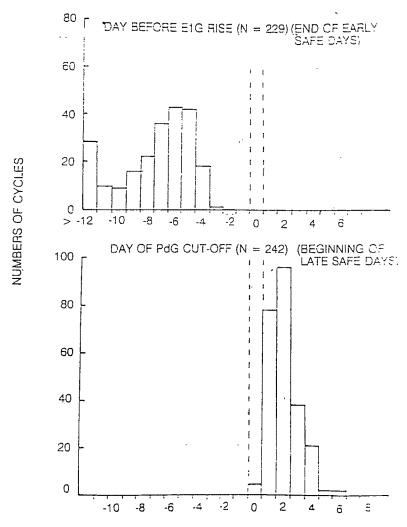

Fig. 2. The confines of the fertile period as defined by the urinary ElG rise and urinary PdG cutoff. Day 0 is the day of the ElG peak value. (Illustration provided by Georgetown University.)

back from this experience, we believe the Home Ovarian Monitor is an important advance in fertility. For couples who did not report infertility, the conception rate for intercourse within the fertile period, as defined by the Monitor, is much higher than the generally accepted figure of 25% per cycle. It is nearer to 70%.

In addition, 5-day sperm survivals to conception are not uncommon; 6-day survival is less common. The longest interval encountered was 8 days (1 in 4000 cycles). The last day of the ElG baseline and BIP is still the problem day; most unplanned pregnancies occurred from intercourse on this day. Women are highly fertile during the second and third ovulatory cycles after 10 months or more of breastfeeding. Appreciation of these findings has made unplanned pregnancies in our user groups a rarity. The Monitor is now available for others to test these conclusions and determine the effectiveness rates in independent studies.

Discussion and recommendations

This session dealt with a variety of topics ranging from new advances in ultrasonography to detect subtle intraovarian changes occurring around the time of ovulation to the presentation of a fully self-sufficient home monitor that allows women to ascertain, in the privacy of their home, their relative fertility status. Described methodologic advances will ultimately allow further simplification of such home tests.

The papers presented demonstrate the considerable effort that has been made in the field of home testing for fertility. Despite this, it is also clear that many of the advances made have yet to be translated into useful simplified tests. Clinical trials are still desperately needed to determine the overall use of such tests for the regularly cycling woman as well as for women in special reproductive statuses (e.g., breastfeeding and perimenopausal). During the next 5 years, the Institute for International Studies in Natural Family Planning plans to fund further studies into the development of simplified tests as well as conduct clinical trials to determine their use. At the same time, we hope to encourage industry to increase their efforts in this same area. Many of the stumbling blocks that need to be overcome are related to the reluctance of industry to

6/0/33242

pursue this area with vigor. This reluctance is obviously because of marketing and patent issues as well as the possible product liability implications of such tests being in the hands of individual couples. It is clear that public education in the realm of fertility awareness will have to go hand-in-hand with the development of tests that allow the self-monitoring of fertility. Close interaction between couples and their physicians will be necessary.

The papers presented reflect advances in our understanding of the process of ovulation, new reagent development for ultimate simplification of the measurements of small molecular weight molecules, results from current available tests, and industry-sponsored advances in assay configuration and simplification. It is becoming apparent that we are approaching the time when simple tests to monitor urinary excretion of estrogen and progesterone metabolites are feasible. In addition, the use of such tests appears very promising. Although considerable work still lies ahead, it is anticipated that new clinical trials of recently developed tests will be underway in the next few years. The Institute for International Studies in Natural Family Planning plans to be at the forefront of these developments and to work to make such a home test, in cooperation with industry, a reality.

SESSION III. THE INTERFACE OF BREASTFEEDING, NATURAL FAMILY PLANNING, AND THE LACTATIONAL AMENORRHEA METHOD

Miriam H. Labbok, Chair Alfredo Pérez, Co-Chair Peter Howie, Rapporteur

Overview and summary: The interface of breastfeeding, natural family planning, and the lactational amenorrhea method

Miriam H. Labbok, MD, MPH, and Peter W. Howie, MDb

Washington, D.C., and Dundee, Scotland

This session explores the use of natural family planning during breastfeeding and the operationalization of the research findings related to the breastfeeding-natural family planning interface into training programs. Worldwide, the vast majority of women breastfeed their infants; in many countries breastfeeding continues for several months. Studies show that women learning natural family planning during lactation, particularly those whose menses have returned, have an increased risk of unplanned pregnancy. Altered hormonal levels may make interpretation of the signs of fertility return (mucus, and so forth) difficult during this time. The lactational amenorrhea method may be a useful adjunct to natural family planning training. (AM J OBSTET GYNECOL 1991;165:2013-4.)

Key words: Natural family planning, breastfeeding, lactational amenorrhea method

This session explores two issues. The first is the use of natural family planning (NFP), especially the ovulation method, during breastfeeding. Worldwide, nearly 100% of women will breastfeed their infants for some period of time. Therefore we must be able to introduce NFP during lactation and do so in a manner that is efficacious. Previous studies show that women learning the method during lactation are at risk of increased unplanned pregnancy rates. The period of lactational menses (i.e., the time when lactation continues but after menses have returned) is apparently the time when unplanned pregnancy is most likely to occur.

The second issue that will be discussed is whether better understanding of lactational amenorrhea could be part of the solution to the problem noted above and incorporated into NFP teaching. We know that breast-feeding patterns can have a profound effect on fertility and that the lactational amenorrhea method (LAM) is an efficacious and natural method for postpartum lactating women. Many commonalities exist between NFP and the LAM. First, both are natural methods that re-

quire no additional medication or insertion of a medical device. Also, both are highly user dependent and require instruction and counseling of the acceptor. Neither method is logistics dependent, and once taught and fully understood, these methods belong to the client for life. Thus these methods are extremely desirable in situations in which other family planning methods are not readily available or are not acceptable.

During this session, a clear consensus emerged among all the speakers and the discussants that LAM should be incorporated into NFP programs. The practical problem is to provide support and counsel to those mothers who wished to use lactational amenor-rhea as an important contribution to effective birth spacing.

Another issue identified during this session was the difficulty of interpreting classic signs of NFP during breastfeeding. The difficulty of interpreting NFP signs was a particular problem after the return of menstruation during breastfeeding but before the resumption of regular cycles, which is generally the phase between the end of LAM and the resumption of regular cycles.

It is also clear that in some communities, lactational amenorrhea will be an important method of fertility control for much longer than the 6 months recommended in the Bellagio guidelines. More work is required to identify those individuals or communities and the breastfeeding practices that are associated with the

6/0/34250

longer lactational amenorrhea. These issues only served to reinforce the consensus among all speakers that the LAM must be incorporated more closely into current NFP programs throughout the world.

It is important to recognize that breastfeeding, especially exclusive breastfeeding, has a profound effect on fertility and on the estrogenic changes that create the signs and symptoms used in various NFP methods. Lactation after menses has returned is not nearly as

protective against unplanned pregnancy. Better understanding of the fertility suppressive effects of lactation and its incorporation into NFP teaching could be part of the solution to this problem.

The following articles and discussions explore these and related issues. It is hoped that the conclusions of this session will provide guidance for NFP policy makers and trainers in the introduction of NFP during breastfeeding.

Is the lactational amenorrhea method a part of natural family planning? Biology and policy

Barbara A. Gross, PhD

Westmead, Australia

The lactational amenorrhea method is a natural method of family planning for women who breastfeed their infants. The underlying physiology results in a natural suppression of ovulation, and the concomitant amenorrhea, induced by exclusive (or almost exclusive) breastfeeding. This in addition to the infant's age of 6 months or less and specific feeding pattern are the parameters used to identify the possible return of fertility. The lactational amenorrhea method provides at least 98% protection against pregnancy. Data from a recent multicenter study of breastfeeding support the use of the lactational amenorrhea method as a natural family planning method. The lactational amenorrhea method can be incorporated into natural family planning programs and teaching. (AM J OBSTET GYNECOL 1991;165:2014-9.)

Key words: Natural family planning, breastfeeding, lactational amenorrhea method, postpartum infertility

The natural child-spacing effect of breastfeeding has been long recognized to be associated with amenorrhea and the duration of breastfeeding, particularly full breastfeeding. Furthermore, in population studies only about 5% to 10% of women have been reported to become pregnant while in lactational amenorrhea. This effect received little attention among populations where breastfeeding was not a common practice. However, the incidence and duration of breastfeeding have been changing in both developed and developing countries, particularly since the early 1970s. In developed countries there has been a return to breastfeeding, and well-educated mothers in the higher socioeconomic groups are more likely to breastfeed and breastfeed longer than those from the lower socioeconomic or im-

6/0/34381

migrant groups.⁷ In some developing countries, particularly in the urban areas, the pattern is the opposite; the more highly educated are less likely to initiate breastfeeding or to breastfeed for only short periods. In rural areas breastfeeding is more prolonged, but there has been a suggestion of a decline in the initiation and duration of breastfeeding in many populations. Economic changes and recent programs for the promotion and support of breastfeeding are associated with abatement and reversal of the decline in many settings.

The duration of lactational amenorrhea in urban and rural populations also differs markedly from country to country, with a range varying from 2 to 3 months up to 2 to 3 years. In many of these populations breastfeeding has provided the major control of fertility; it delays the return of bleeding/menstruation and ovulation, but it does not permanently prevent pregnancy. The impact of a decline in the duration of breastfeeding and its concomitant effect on lactational amenorrhea, particularly in developing countries, has been high-

lighted by several writers.⁸ For example, in Senegal, where the average duration of breastfeeding and lactational amenorrhea is 19 and 15 months, respectively, a 50% reduction in the duration of breastfeeding would require an increase in contraceptive use from 11% to 35% to maintain current fertility rates.⁹

Natural family planning programs and lactational infertility

Breastfeeding has not been recognized for its important natural effect on fertility or as a natural family planning (NFP) method in most NFP programs in spite of the knowledge presented above. Many NFP programs recognize a 7- to 12-week period of natural infertility after childbirth, which is extended by breastfeeding. This is based on studies of breastfeeding women in which basal body temperature^{10, 11} and endometrial biopsy¹² were used as indicators of the probability of ovulation preceding the first postpartum bleed. In these studies most of the women breastfed for 3 to 6 months, with the period of full (or exclusive) breastfeeding even shorter, and solid and liquid supplements (cereal and juice) were introduced as early as 3 to 6 weeks after delivery.

Studies by Gross and Eastman¹³ and Brown et al.¹⁴ compared mucus symptoms with serum levels of estrogens and progesterone or their urinary metabolites. They found longer periods of infertility associated with longer durations of full breastfeeding. These findings were incorporated into teaching programs associated with the ovulation method and the symptothermal methods developed in Australia. These programs suggest that couples begin observing and recording their signs of fertility from 3 to 5 weeks after delivery. If a couple wants an almost zero risk of pregnancy, they are often counseled to abstain from the seventh or tenth postpartum week until they have evidence of ovulation by a sustained thermal shift of at least 4 days, thus resulting in a long period of abstinence during a period of relative infertility.

Another choice presented by some NFP programs is to wean the baby to facilitate the return of cyclicity and the application of NFP. In other instances couples using NFP methods based on cervical mucus observations are instructed that they can be guided by their observations to determine the days of infertility and possible fertility and to apply the rules for avoiding pregnancy. The mucus signs can be confusing for some, however, and do not always reflect the underlying ovarian activity; signs may suggest ovulation when it is not occurring or fail to indicate ovulation when it does occur. This can result in unnecessary and prolonged abstinence, although this may be acceptable to a couple with a strong desire to avoid another pregnancy. At the same time, pregnancy is possible, although not probable. The short

duration of lactational amenorrhea along with a suggested high incidence of first ovulatory bleeds, in spite of low pregnancy rate, were the major influences on NFP programs of the 1970s.

Essentially the western breastfeeding patterns of the 1970s forced on NFP teaching nonacceptance of lactational amenorrhea as a natural method of family planning. Teaching programs with this viewpoint have been extended to the developing countries, where there has been and still should be a reliance on lactational amenorrhea as an effective natural method of birth spacing but with some guidelines as suggested below.

Lactational amenorrhea

The mechanism of lactational amenorrhea is still not well understood. Prolactin levels are elevated during pregnancy and continue to be elevated above normal prepregnancy levels during lactational amenorrhea, but they gradually return to normal as ovarian function returns. Prolactin levels increase in response to suckling and may be a marker of the altered hypothalamic-pituitary axis or may have a direct action on fertility, perhaps at the level of the ovary. Ovulation is prevented or follicular development may be altered, resulting in deficient corpus luteum function, altered endometrium, and infertility. This inhibition of ovarian function can continue even after bleeding resumes, explaining in part the lower than expected pregnancy rate while breastfeeding continues.

More recent studies15-18 have shown that menses can be delayed on average for 7 to 9 months even in wellnourished western women. Table I summarizes Australian studies indicating the return of vaginal bleeding between 33 to 48 weeks (7½ to 11 months) after delivery, with individual women resuming ovulation as early as 12 weeks and others delaying up to 2 years. Twentyfive percent to 30% of the women resumed menstruation while fully breastfeeding, with varying frequency and duration of breastfeeding episodes. In other populations such as in Chile and Mexico, the duration of amenorrhea is shorter in spite of full breastfeeding of high frequency. In most of the recent studies, 25% to 30% of women have evidence of ovulation (as indicated by adequate levels of serum progesterone or urinary pregnanediol) before the first bleed, but many of these ovulations show evidence of inadequate luteal function.17 Furthermore, the incidence of ovulatory first bleeds occurring during full breastfeeding and in the first 6 months has been shown to be low, with a suggested pregnancy risk of less than 2%.19

The lactational amenorrhea method

An individual couple can rely on breastfeeding to provide natural protection against pregnancy for at least 6 months, provided the mother has no return of

bleeding (ignoring any bleed for up to 56 postpartum days) and the baby is being fully, or almost fully, breastfed. These guidelines provide less than a 2% risk of unplanned pregnancy.

The above statement is now often referred to as the *Bellagio Consensus Statement*.^{19, 20} When put into practice, the statement defined the lactational amenorrhea method (LAM)—a natural method of family planning based on the lactational amenorrhea produced by the ovulation suppression effects of full breastfeeding during the first 6 months of life. This method can be illustrated by an algorithm, or decision tree, developed initially by Miriam Labbok²¹ (Fig. 1) and modified according to the results of the recent research that formed the basis of the Bellagio Consensus Statement.²²

The Bellagio Consensus Statement was issued from a meeting of 25 scientists in Bellagio, Italy, convened by Family Health International and the World Health Organization. The Consensus Statement's pregnancy rate of less than 2% was based on data from three prospective studies of pregnancies occurring during lactational amenorrhea and full breastfeeding in the first 6 postpartum months.19, 20 This figure was then supported by the calculation of the probability of pregnancy based on observed premenstrual ovulation rates during the first 6 months of lactation. The pregnancy rate was assumed to be 25% of the ovulation rate, although fecundity of ovulation during breastfeeding is thought to be much lower than 25%. With this high estimate for comparison, data from 10 small prospective studies (25 to 113 subjects) using hormonal evidence of returning ovulation gave estimated pregnancy rates up to 2.9%.20

The Bellagio Consensus Statement indicates that if these guidelines are adhered to (i.e., LAM is used), then 98% to 100% of couples will have warning of impending ovulation and can then make a decision on an alternative method of family planning, including NFP.¹⁹

Three-center breastfeeding/NFP study

Preliminary data from a three-center study of NFP and breastfeeding in the United Kingdom, Canada, and Australia are described in more detail in the another article in this issue (Kennedy et al.).

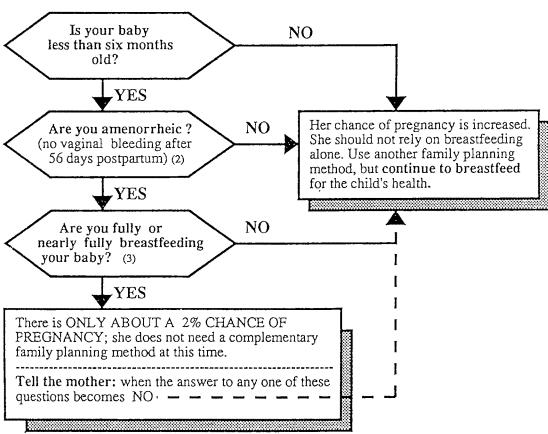

Table II illustrates the mean days of first bleed, first ovulation, and average number of days of protection provided by the Bellagio guidelines. The mean day of first bleed was very similar in Australia and Canada (229.6 \pm 112.9 and 221.04 \pm 88.5 days, respectively), and this was approximately 30 days longer than in the United Kingdom (198.9 \pm 114.5 days). The average number of days of infertility provided by LAM/Bellagio guidelines was 134, 132, and 112 days, respectively, for Australia, Canada, and the United Kingdom.

In all cases in Australia, the last day of protection provided by the Bellagio guidelines preceded the estimated first day of ovulation. In one case the first "bleed" was actually 6 days of spotting. If the spotting were discounted, one adequate and normal ovulation preceded both the Bellagio cutoff the first bleed in one woman who was fully breastfeeding. In addition, the first ovulation was not always an adequate ovulation as defined by pregnanediol levels (i.e., >9 nmol/24 hr) or length of the luteal phase (≥10 days), in that the risk of conception for any one ovulation is only 25% or less, and the guidelines therefore provided even greater protection than predicted.

In Canada, the mean first estimated day of ovulation as determined from the urinary estrogen peak was 227.6 ± 90.9 days, whereas the first ovulation with an adequate luteal phase was at 264.8 ± 108 days. The range was wide, 60 to 405 and 94 to 494 days, respectively. The Australian data are not complete, but with the preliminary data as a base, the first ovulation occurred between 76 and 455 days, at a mean of 237 days. In the Sydney study the earliest ovulation with an apparently adequate and normal-length luteal phase was

^{*}Range in parentheses.

Ask the mother:

- (1) It must be noted that these guidelines are conservative. Women who follow these guidelines after six months postpartum, or who have experienced only one vaginal bleed, may still have some decreased fertility if the recommended optimal breastfeeding behaviors are followed. Furthermore, in many areas of the world, women may breastfeed for 18-24 months and remain amenorrheic for 12 months or more. These women may remain infertile for 12-15 months postpartum.
- . (2) Spotting that occurs during the first 56 days is not considered to be menses.
 - (3) "Full" breastfeeding includes exclusive or almost exclusive breastfeeding (occasional tastes of ritual foods or water), day and night, according to recommendations. "Nearly full" breastfeeding means that occasional non-breast feeds are given.

Fig. 1. Use of LAM for child spacing during the first 6 postpartum months.

on day 76, in a woman who weaned her baby on postpartum day 63. These findings suggest that individual women should begin to use an alternative method of family planning, including NFP, once they begin supplements after 6 months during lactational amenorrhea, if they wish to avoid pregnancy. However, it is obvious from the data that many women will remain amenor-rheic and/or anovulatory well beyond 6 months or beyond the introduction of supplements (see Fig. 1).

The shortest intervals between the Bellagio guidelines and the first ovulation in the Australian group were 8 and 15 days in two subjects who resumed bleeding while fully breastfeeding. As indicated above, 6 days of spotting heralded the ovulation for one woman and 1 day of bleeding and 3 days of spotting for another. The mean interval between the postpartum days by LAM to the first ovulation was 103 days (range, 8 to 272) and to the first normal/adequate ovulation, 134 days (range, 11 to 311).

The appropriate use of LAM results in a 2% pregnancy rate. The use of NFP, particularly the cervical mucus methods, may assist a woman to recognize the pending follicular development and ovulation. In three Australian studies of cervical mucus observations during breastfeeding, no pregnancies occurred before the first bleed, whether the bleed occurred during full breastfeeding, during partial breastfeeding, or after weaning. Studies in Chile also indicate high effective-

^{*}Includes the first 42 postpartum days for all women.

ness of the ovulation method, particularly during full breastfeeding and during the first 6 months.²³

One of the disadvantages of using cervical mucus observations to predict ovulation may be the inability to recognize the infertile days because of the continuous and confusing mucus patterns that result in prolonged abstinence. 14. 24.26 An interesting comparison of the number of days of abstinence imposed by NFP observations with those imposed by LAM can be made by using the data from the multicenter study described in the article by Kennedy et al. in this issue (Table III).

As shown in Table II, the number of days of protection provided by the Bellagio guidelines was on average 126 days (range 55 to 183). The calculated number of days of abstinence that would have been required based on mucus observations (and basal body temperature in some cases) during this period of LAM use ranged from 0 to 97 days (mean, 21 days), with up to 58.4% of these days actually requiring abstinence (with a possible maximum of 69%). By using NFP, 20 of 75 couples would have had to abstain for more than 20% of the days indicated as infertile by the LAM criteria.

By contrast, 30 of 75 couples identified less than 10% of the infertile days as requiring abstinence; their fer-

tility signs were closely related to the infertility indicated by LAM. It could be argued that the frequency of intercourse is naturally low during this time,²⁷ but this could also be due to lack of confidence in their infertility based on NFP signs, a low libido, fatigue, or other reasons. The point of the analysis is that LAM can minimize the time required for abstinence and result in a low risk of pregnancy.

Future research

Many questions remain. What are the limitations of LAM? Can the 2% risk of pregnancy with LAM be further reduced? Is spotting a warning of impending ovulation for those likely to be at risk of becoming pregnant? Can a previous lactation experience be used as a guide?

It is also important to define what constitutes full breastfeeding. Is there a minimum number of breastfeeds by day and/or by night? Is there a minimum duration of a suckling episode or total suckling during a day? Is there a maximum interval between feeds? Is this more important by day or by night? Is there a minimum intensity of suckling? Does supplementation and pacifier use in small amounts or after suckling af-

[†]Ovulated before first bleed but after weaning at 63 postpartum days.

[†]The maximum possible number of days of abstinence is 183 - (42 + 14) = 127 days, where 14 is the number of days required after day 42 to describe the infertile pattern.

[‡]Greatest possible proportion is 69.4%.

[§]Range in parentheses.

fect the physiologic impact? How much other food (liquid or solid), by quantity or frequency or caloric content, can be included as almost fully breastfeeding? How much do early postpartum factors in the establishment of breastfeeding affect subsequent fertility? What characteristics of the infant, the mother, and the breastfeeding patterns affect lactational infertility? Are there environmental factors that influence breastfeeding patterns or physiologic responses?

Policy questions

A number of policy questions have yet to be resolved. Should LAM be included in NFP training and teaching programs? What adjustments to teaching need to be made both to support breastfeeding as well as to initiate NFP during breastfeeding? What education and motivation of teachers are needed to increase confidence in LAM? What ancillary education programs are needed to inform teachers and clients of the factors that maximize the infertility effects of breastfeeding? What support is needed for clients to benefit from the LAM? How should NFP methods be applied after return of menstruation?

Conclusions and recommendations

The natural protection afforded by LAM should be incorporated into the teaching of NFP. It can provide couples with security in their postpartum infertility, minimize the abstinence that might otherwise be necessary as a result of confusing mucus or basal body temperature observations, and allow couples to enjoy their new infant and renew their relationship. The interface with NFP is obvious. The woman can still be aware of and observe symptoms that can alert her to the possibility of approaching fertility. More detailed observations and charting should begin at the end of the natural protection provided by LAM, and application of the appropriate method of NFP should then be made to avoid pregnancy.

The studies carried out in collaboration with Family Health International were under the direction of Kathy Kennedy and with collaborating scientists Dr. Suzanne Parenteau-Carreau, Serena, Montreal, Canada, and Dr. Anna Flynn, University of Birmingham, United Kingdom. Urinary estrogen and pregnanediol assays were carried out by Joanne Holmes and Gillian Barker under the direction of Professor James Brown at the Department of Obstetrics and Gynecology, Royal Women's Hospital, Carlton, Melbourne, Australia, and also the help of Sheila Kippley (Couple to Couple League International, Inc., Cincinnati, Ohio).

The natural family planning—lactational amenorrhea method interface: Observations from a prospective study of breastfeeding users of natural family planning

Kathy I. Kennedy, MS, Suzanne Parenteau-Carreau, MS, Anna Flynn, MD, Barbara Gross, PhD, James B. Brown, PhD, and Cynthia Visness

Durham, North Carolina, Serena and Ontario, Canada, Birmingham, England, and Westmead and Melbourne, Australia

Methods of natural family planning are sometimes difficult for women to use during lactation. When this is so, the lactational amenorrhea method may prove useful. Researchers agree that a fully breastfeeding woman who is amenorrheic is 98% protected from pregnancy for up to 6 months after delivery. The fertility status of 74 users of natural family planning during the time they would have been protected by the lactational amenorrhea method is examined. Underlying hormonal profiles show that there was little ovarian activity during this time. Eight ovulatory events occurred during the period of protection by the lactational amenorrhea method, of which four fulfilled minimum criteria for adequacy; there were no pregnancies during this period. However, some women did report experiencing fertile mucus symptoms during this time that were often unrelated to estrogen production. Using the lactational amenorrhea method rather than natural family planning allows them to avoid unnecessary abstinence. (AM J OBSTET GYNECOL 1991;165:2020-6.)

Key words: Natural family planning, breastfeeding, lactational amenorrhea method, postpartum infertility

Lactational amenorrhea method (LAM) is the informed use of lactational amenorrhea, during full or nearly full breastfeeding, as a means of avoiding pregnancy for up to 6 months after delivery. It is based on the Bellagio Consensus Statement, a summary of 13 studies from eight countries that concluded that "breastfeeding provides more than 98% protection from pregnancy during the first 6 months postpartum if the mother is 'fully' or nearly fully breastfeeding and has not yet experienced vaginal bleeding after the 56th day postpartum."^{2,3}

Natural family planning (NFP) methods have been adapted for use during lactation and have been taught and used successfully by various NFP programs around

the world. However, unlike the usual cervical response to estrogen production in the normally cycling, non-lactating woman, cervical mucus production during lactation does not always reflect the underlying ovarian physiology. ^{4,5} During lactation, cervical mucus production is usually a consequence of estrogen secretion. However, when mucus with fertile characteristics is produced in the absence of ovarian activity and hormone production, the use of NFP during breastfeeding can be difficult. If this unexplained mucus production is irregular, establishment of a basic infertile pattern could be especially difficult and could require several weeks of abstinence following NFP rules.

The frequency of unexplained fertile-type mucus production during lactation is not known, although it was observed, with confirmation by ovarian ultrasonography, in 18 breastfeeding women, (not randomly selected),⁴ and a similar case is also described herein. Consequently, it is of interest to know whether the use of LAM for up to 6 postpartum months by experienced NFP users would be useful, especially in terms of the amount of postpartum abstinence recommended by NFP that could be averted by using LAM.

A study of the use of the symptothermal method (STM) by breastfeeding women was conducted through Serena, Montreal, Canada; Westmead Hospital in Sydney, Australia; and the Birmingham Maternity Hospital in England. The purpose of the study was to evaluate the use of STM by breastfeeding women to learn

Supported by funds from Family Health International (FHI) and the Institute for Reproductive Health, through their cooperative agreements with Agency for International Development (AID). whether it is biologically reasonable to use STM during breastfeeding to predict the recovery of fertility, and to determine whether NFP symptoms are related to the hormonal pattern that is presumed to cause them. This study permitted three types of observations related to the interface between NFP methods and LAM: (1) a description of the mucus symptoms and estrogen production during the period of natural protection as defined by LAM; (2) an example of the kind of woman who would benefit by substituting LAM for NFP in the first 6 postpartum months; and (3) a description of the single unplanned pregnancy and how it is related to both LAM and STM.

Method

Twenty-five experienced STM users were recruited in each center. The women were normal and healthy, as were their babies; they intended to use STM to prevent pregnancy and to breastfeed for at least 6 months. Each day they completed a detailed two-page diary sheet that covered questions about infant feeding and about their natural fertility symptoms (qualities of cervical mucus, basal body temperature, and, for some women, the position of the cervix). The women also collected a timed urine sample every day from which levels of estrogen⁶ and progesterone⁷ metabolites were measured and from which the estimated day of peak estrogen production was determined by the laboratory at the Royal Womens' Hospital of the University of Melbourne, Australia. One woman was not included from parts of the analysis because there were too many missing urine samples to draw conclusions about her fertility status.

"Ovulation" is said to have occurred if a rise in total urinary estrogen above 10 μ g/24 hr is seen, followed by a rise in pregnanediol glucuronide to at least 4.5 μ g/24 hr. The ovulation was called "inadequate" if pregnanediol glucuronide excretion was low (\geq 4.5 but <9.0 μ g/24 hr) and/or if the luteal phase lasted less than 10 days. If pregnanediol excretion was greater (\geq 9.0 μ g/24 hr) and if the luteal phase was 10 days or

longer, the ovulation was called "adequate" (or sometimes "possibly adequate" because the criteria for adequacy are the bare minimum values associated with normal cycling).

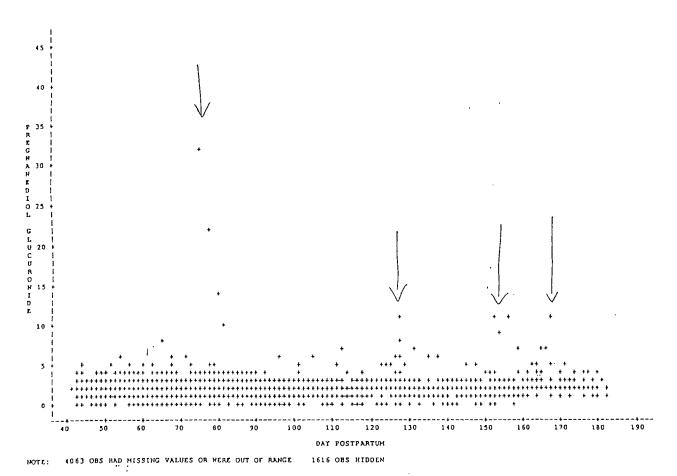

Follicular development is considered to be present when the concentration of total urinary estrogens is $\geq 15 \,\mu g/24$ hr, particularly when it is part of a rising pattern. (Concentrations between 10 and 15 $\,\mu g/24$ hr could possibly reflect follicular activity when they are part of a pattern of increasing estrogen concentration, and would be expected in only a minority of women with very low baseline levels of estrogen.)

Results and explanation

The duration of natural protection from LAM. According to LAM a breastfeeding woman can experience up to 183 days (6 months) of natural protection from pregnancy as long as she remains amenorrheic and breastfeeds her baby without supplements. When the LAM guidelines were applied in this study, the period of natural protection ranged from 54 to 183 days, averaging 4.1 months (Table I). In each study center some women did experience the maximum number of days of LAM protection (four, six, and two women in Montreal, Sydney, and Birmingham, respectively). The women in all three centers usually began supplements by the end of the sixth month, and the duration of LAM protection ended at the commencement of supplementation in 16, 13, and 16 women in Montreal, Sydney, and Birmingham, respectively.

Abstinence by use of STM during LAM protection. During this period of natural protection according to LAM, days 0 to 97 would have been days in which abstinence was recommended if the STM was used correctly. Expressed in percents, during 0% to 58% of the time that was infertile according to LAM, abstinence was recommended according to STM (Table I).

Mucus symptoms during LAM protection. We also see in Table I that from 0% to 67% of the days of natural LAM protection are days on which fertile mucus symptoms occurred. Some of the women reported

The Lactational Amenorrhea Method (LAM) is a natural method of family planning for breastfeeding women. It should be incorporated into Natural Family Planning (NFP) programs and teaching.

Fig. 1. Distribution of number of days between end of Bellagio protection (LAM) and the first day of ovulation as estimated from urinary pregnanediol levels. (Note that ovulation may not have been normal ovulation with adequate luteal phase.) (Illustration provided by Georgetown University.)

no fertile mucus during this period. Some of the reports of fertile-type mucus were accurate reflections of the underlying ovarian activity, and they preceded the first ovulations, albeit usually inadequate ones. In other cases, however, the mucus symptoms were deceptive, portraying fertility when there was in reality no estrogen production.⁴ In this situation NFP can be very difficult to use (see following case description).

In Fig. 1 progesterone production—the hormonal consequence of ovulation—is reported as micromoles of urinary pregnanediol per 24 hours. The four potentially adequate cycles can be seen easily as the four episodes in which pregnanediol rose above the minimum value associated with normal luteinization (9 µmol/24 hr).

Only one of these four potentially adequate episodes (the first) reflects a significant amount of pregnanediol excretion. In this case, during the 2 weeks immediately before ovulation, the woman breastfed her baby as seldom as five times in a 24-hour period, with interepisode

intervals as long as 9½ hours. She also reported that the baby had colic and that the breastfeeds were therefore brief. During about half of this period, she breastfed only during the day and not at all at night. She had also given her baby a bottle of milk or formula for 3 days in the week before ovulation. Since she had not yet given the baby supplemental food every day for 7 consecutive days, she was not yet categorized in this study as "supplementing"; however, this pattern would be considered less than full breastfeeding.

The three remaining potentially adequate cycles in the lower panel of Fig. I were each characterized by a 10-day luteal phase. The likelihood is very low that such a brief luteal phase could have characterized a cycle capable of sustaining a pregnancy. In Fig. 2 these three cyles with 10-day luteal phases are counted as "adequate" in an inverse life table depiction of the percentages ovulatory during the period of LAM protection because there is a slim chance that the event was fully fertile.

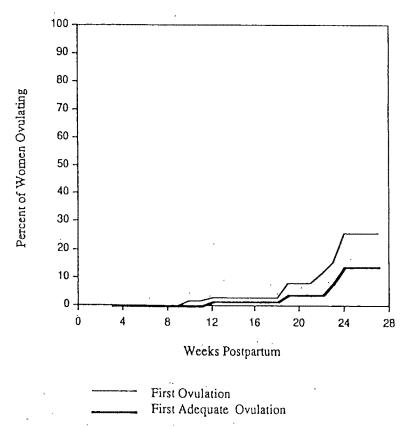

Fig. 2. Time to first evidence of ovulation and first adequate ovulation during LAM protection in all three centers, N = 74.

Altogether, eight out of 74 women for whom hormone data are available (11%) experienced symptoms of ovulation. In four of these cases the ovulation could possibly have been adequate (5%), although in only one case was the luteal phase greater than 10 days (1%). The life table rates for women experiencing the first ovulation by the sixth month of LAM protection (0.257) and the first possible adequate ovulation (0.139) are higher than the absolute percents mentioned above (11% and 5%) because most women were censored from the life table during the fifth and sixth postpartum months; at this point they were regularly supplementing the baby's breastmilk diet with other foods and therefore had ceased to be protected by LAM because they were no longer nearly fully breastfeeding.

To estimate the probability of pregnancy, both the absolute and life table percentages of women ovulating must be multiplied by a factor of 0.25 or lower. Since in even normally cycling, nonlactating women, no more than 25% will conceive during any given cycle, 8-10 the maximum 6-month life table pregnancy rate falls between 1.25% and 6.23%. It would be prudent, however, to remember that only one ovulation was characterized by strong evidence that it was normal; therefore we would expect a much lower pregnancy rate than this range suggests.

What kind of STM user would most benefit by using LAM? It seems intuitively obvious that any woman who is knowledgeable about LAM, who plans to exclusively breastfeed her baby for at least 6 months, and who makes an informed choice to use LAM is a good candidate for the method. We would like to give a cautionary note; if her previous breastfeeding experience reflects an early return of fertility, she may wish to take this into account in her informed choice. STM users, particularly those for whom STM rules recommend a great deal of abstinence even during amenorrhea and exclusive breastfeeding, might be especially happy to substitute LAM for STM for 6 months. For example, one woman in the Montreal center contributed most of the reported days of fertile type mucus, and she was definitely infertile during her entire 6 months of LAM protection. Fig. 3 displays her mucus symptoms and her estrogen profile for this period. This woman experienced persistent mucus, which she, as an experienced NFP user, perceived to be fertile, whereas her estrogen production remained persistently flat. She may have been an ideal candidate for LAM, since the proper use of STM required abstinence for more than a third of these days.

The unplanned pregnancy vis-à-vis LAM and STM. This study was not designed to yield an effectiveness

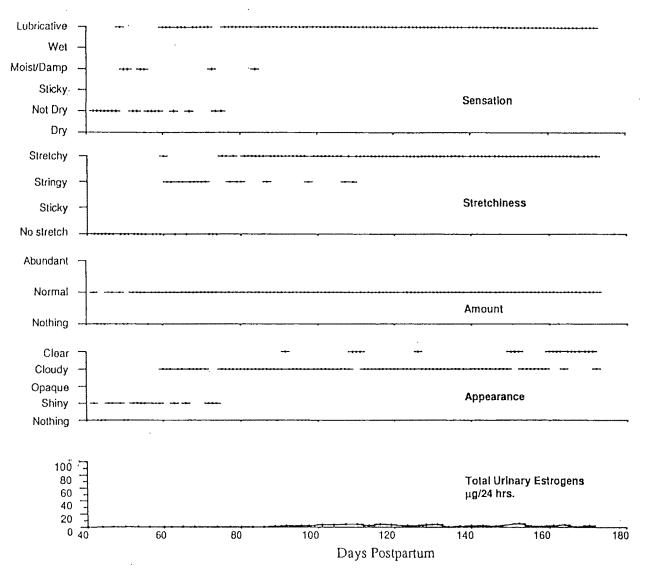

Fig. 3. Mucus symptoms and estrogen levels for mother No. 22, Canadian center. (Illustration provided by Georgetown University.)

rate for either LAM or STM. The women in the study were actively using STM as it is taught by their respective centers. One unplanned pregnancy occurred in a woman at the Montreal center at the end of her sixth postpartum month during full breastfeeding (Fig. 4). At the estimated time of the conception, she was breastfeeding an average of 10 times in 24 hours. She was not, however, still amenorrheic and, hence, no longer using LAM. She had had two bleeding episodes and an "inadequate" ovulation before the cycle in which she conceived.

The day of peak estrogen excretion (the estimated day of conception) was postpartum day 182. She had had intercourse 5 days previously, during a time when she did not report fertile-type mucus (it was described as sticky and shiny), and the woman did not believe herself to be fertile. Fertile-type mucus appeared 2 days after the day of sexual relations and lasted for 2 days.

The woman considered herself fertile for 3 days (the 2 days of fertile mucus plus 1 day). The conception probably occurred the day after that. Correct use of STM recommended abstinence from day 169 through day 184. Although her symptoms were not necessarily "fertile," they were different from—and elevated above—her basic infertile pattern. This was particularly significant because she had already experienced two bleeding episodes, which should have motivated her to attend to the rules for abstinence.

There are several points of note regarding this pregnancy and LAM. Since this woman had experienced two bleeding episodes before the conception, it did not occur during the period of LAM protection, since vaginal bleeding episodes are nearly always the consequence of some form of ovarian activity (e.g., ovulation, inadequate ovulation, estrogen withdrawal because of the collapsed follicle). The high level of natural pro-

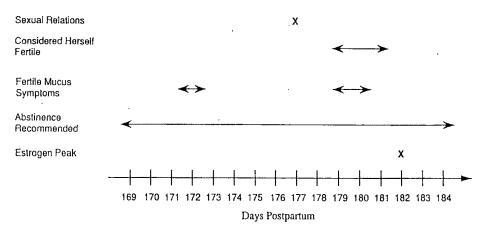

Fig. 4. Unintended pregnancy in mother No. 2, Canadian center.

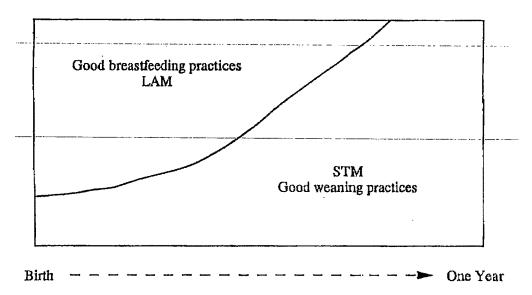

Fig. 5. Suggested emphasis in NFP-breastfeeding counseling. (Illustration provided by Georgetown University.)

tection provided by LAM has ceased once lactational amenorrhea has ended. For NFP users who use LAM during the first 6 months, the occurrence of bleeding is a warning to be taken seriously. Perhaps if this woman had appreciated the significance of her bleeding episodes, she would have been more attentive to her symptoms and applied the rule more exactly.

Comment

These data from the NFP and breastfeeding study suggest that the option to use LAM during the first 6 postpartum months may be helpful to some couples and appears to pose no additional risk of pregnancy in terms of the rates of adequate ovulation during the period of LAM protection. NFP programs would need to incorporate the teaching of good breastfeeding skills and principles to make this effort successful.

This analysis implies at least three potential programmatic recommendations. These recommendations

are speculative but would appear to be logical corollaries of the findings reported here in the context of modern NFP programs. The first is that the use of LAM among NFP users should be encouraged when possible. There is a risk of pregnancy, but it appears to be no greater than the risk associated with using other NFP methods. To their benefit, couples could avoid unnecessary abstinence but, perhaps more important, could be relieved of the possible frustrations associated with trying to identify a dynamic basic infertile pattern.

Second, couples should be urged to pay very serious attention to the return of menses or bleeding. Because the STM rules require couples to abstain until the observed postovulatory phase in the first three cycles, there can be a considerable time of abstinence, but it may be preceded by an abstinence-free phase if LAM is used.

Third, in postpartum NFP programs good breastfeeding skills or principles should be taught. By helping women to be successful breastfeeders, NFP programs may also observe parents who are more confident regarding both the care and nourishment of their child and their protection from pregnancy, longer natural durations of lactational infertility, fewer frustrations for couples and teachers, and greater professional fulfillment for teachers. All involved may also be pleased to know that they are reducing their child's risk of many infections and some chronic diseases. These are some potential benefits that NFP programs may consider measuring and cultivating as they develop programs and strategies for testing the integration of LAM and NFP.

Our support of breastfeeding families might take a profile suggested in the continuum in Fig. 5. At first, greater educational effort could be focused on breastfeeding skills (such as how to help a baby attach to the breast) and on breastfeeding principles (such as feeding the baby frequently day and night, avoiding bottles and pacifiers, and the like). Also, of course, an overview of how to use NFP in the postpartum period could be given so that LAM rules can be followed as soon as LAM protection expires. Gradually the couple will need to know about good weaning practices and given detailed information about how to handle at least the first three menstrual cycles. NFP instructors would need to acquire more skill and more knowledge, but these would be germane to teaching couples to be in charge of their own natural infertility and recovery of fertility, since infant feeding practices are directly related to postpartum fertility.

We gratefully acknowledge the help of the technical staff responsible for conducting the hormone analyses and the NFP teachers who conducted the field work, namely, Dr. Meg Smith, Joanne Holmes, Gillian Barker, Denise La Flamme, Lise Trepanier, Gail Byrne, and Anne McCarthy. Finally, our deep gratitude goes to the mothers who persevered in providing daily diary sheets and urine samples over months and years.

Ultrasonographic patterns of ovarian activity during breastfeeding

Anna M. Flynn, MD,^a M. Docker,^b James B. Brown, MD,^c and Kathy I. Kennedy, MS^d Birmingham, England, Victoria, Australia, and Durham, North Carolina

In this study, ultrasonography was used to detect follicular activity in lactating women, and these findings were related to the underlying hormonal profiles and to the mucus symptom. A number of different patterns of follicular development were seen before the women returned to normal fertile cycles during the period that was previously considered to be characterized by ovarian quiescence. Some of the transitory patterns of follicular activity were reflected in rising hormone levels and patterns of fertile mucus that were sometimes confusing for these lactating women who were using natural family planning. (AM J OBSTET GYNECOL 1991;165:2027-31.)

Key words: Natural family planning, lactating women, ultrasonography, follicular growth, cervical mucus

Ultrasonographic examination is a well-established technique for monitoring follicular and ovarian activity in both spontaneous and induced ovulatory cycles, and there are several publications that describe the patterns of follicular growth and development that are found in different clinical situations. ¹⁻⁴ In contrast, ovarian and follicular activity in women who experience returning fertility during and after lactation is less well documented. ^{5, 6} Shaaban et al. ⁶ have studied lactating Egyptian women between 6 and 12 months after delivery, but many of these women were no longer amenorrheic. Flynn et al. ⁵ observed only two women during weaning.

Hormone profiles have been used to describe the endocrine and gonadotropin activity in the hypothalamic-pituitary-ovarian axis. These studies have contributed to an understanding of the underlying physiology that is associated with lactation infertility. To ther researchers have studied the relationship between ovarian hormone production and women's observations of cervical mucus and/or basal body tem-

Reprint requests: Anna M. Flynn, MD, Natural Family Planning Centre, Department of Obstetrics and Gynecology, Birmingham Maternity Hospital, Queen Elizabeth Medical Centre, Edgbaston, Birmingham B15 2TG, United Kingdom. 6/0/34248 tation, breastfeeding women often experience fertiletype mucus symptoms at times that are unrelated to ovulation. ¹² Consequently, such women can have difficulty in using natural family planning at this time without on the one hand, an undue (and often unnecesssary) amount of sexual abstinence or on the other hand, exposure to the risk of an unplanned pregnancy. The aim of this project was to (1) observe (through serial ultrasonography) and describe the different pat-

perature. 10-13 Although a peak mucus symptom is very

frequently associated with ovulation even during lac-

The aim of this project was to (1) observe (through serial ultrasonography) and describe the different patterns of follicular growth and development before normal fertile cycles become established in the lactating mother and (2) to relate these patterns to the underlying hormonal profiles and to the cervical mucus symptoms.

Methods

Beginning at 6 weeks after delivery, 18 lactating women collected daily time samples of urine, which were stored frozen at 17° C and subsequently analyzed for total urinary estrogen¹⁴ and pregnanediol¹⁵ concentrations. Each women completed a daily record of mucus observations and basal body temperature. Each woman also kept a daily record of the number of breast feeds, bottle feeds, and/or solids given to the baby both over the day and during the night.

Follicular tracking was carried out with a G.E. RT 3000 real-time scanner with a 5 MHz phased array sector probe, each woman who was examined had a full bladder, and the abdominal scanning technique was used. Scanning was begun during the twelfth week and was continued at weekly intervals until the ultrasonographer noted developing activity and/or the lactating woman found that her clinical indicators (mucus, cervix, and basal body temperature) suggested that she

was potentially fertile. When either one or both of these conditions were present, follicular tracking was carried out at more frequent intervals until the ovarian activity decreased or the follicle ruptured whether or not the ovulatory event occurred.

In the same manner that was used to detect ovulation of normal reproductive cycles in nonlactating women, the ultrasonographer looked for follicular rupture with possible ovulation and the following indicators of fertility: the development of a follicle with a maximum diameter of 18 to 25 mm over a period of 3 to 6 days and its subsequent rupture or decrease in volume by 50% over 24 hours; the presence of fluid in the pouch

of Douglas, if seen, around the time of rupture; thickening of the endometrium, if seen; and the presence of a corpus luteum within 24 to 48 hours after follicular rupture. All data collection procedures were followed until after the second normal postpartum ovulatory cycle.

Results

Table I outlines the different patterns of follicular development that were found in the women who were studied. No consistent serial pattern emerged; in some women, multiple folliculogenesis was quickly followed by normal fertile cycles, whereas in others, several transitional patterns occurred before fertility became established. Ultrasonographic records were examined for episodes of follicular development and ovarian activity. Each episode was categorized by the pattern presented, some of which are illustrated in Figs. 1, 2, and 3.

Multiple folliculogenesis. Multiple folliculogenesis was a very common finding during the early stages of returning fertility in almost all of the lactating women who were studied. In these women, several small follicles with a typical diameter of approximately 8 mm were observed in one or both ovaries. The number varied but ranged between 3 and 20. Their appearance

Am J Obstet Gynecol

was episodic and there were intra- and interwoman variations in the duration of these multiple follicles.

In general, these follicles caused no increase in the concentrations of estrogen and progesterone metabolites, and consequently, the women observed no increase or change in the cervical mucus and patterns (Fig. 1). Eventually, in all cases, one follicle became dominant and the others regressed.

Unruptured follicles. Three types of unruptured follicles were observed: the luteinized unruptured follicle, the atretic follicle, and the persistent follicle (cyst). In the first two situations the follicle grew slowly and reached a maximum diameter that was somewhat smaller than normal. The follicle did not rupture but slowly decreased in size over the subsequent days and finally disappeared.

In the luteinized unruptured follicle, estrogen and pregnanediol levels increased without reaching the concentrations that are found in the normal ovulatory cycle (Fig. 2). In the atretic follicle there was no increase in the pregnanediol concentrations (Fig. 1).

In the persistent unruptured follicle, ultrasonographic findings showed the growth and development of what appeared to be a normal follicle. Development continued, and in some cases the follicle increased in size to a diameter of 30 mm, which was maintained for weeks until it finally ruptured or regressed. Some of these large persistent follicles were associated with estrogen excretion as well as the production of fertiletype mucus for long periods and with a pattern that was impossible to distinguish from that of the normal fertile phase (Fig. 2).

Recurrent persistent follicles. We found this pattern in only one mother who intensively breastfed her infant for almost a year. From approximately 6 months after delivery, a follicle developed that reached a maximum diameter of at least 18 mm over 1 to 3 days and then ruptured within 24 hours. Initially, these episodes occurred at 60- to 90-day intervals, but later in lactation they recurred at intervals of 30 days. These follicles did not produce any increase in ovarian hormones nor were they accompanied by any clinical signs of fertility or vaginal bleeding until the infant was weaned at 57 weeks when there was a sudden resumption of fertile cycles (Fig. 3).

Delayed ovulation. In this pattern, the leading follicle developed normally to its maximum diameter at which time an estrogen peak was observed in the urine. However, instead of rupturing as expected, the follicle maintained its size for 2 to 3 days before it ruptured. Hormone concentrations and the length of the luteal phase were similar to those for the normal fertile cycle and menstruation followed (Fig. 2).

Comment

Until recently, the period of lactational amenorrhea had been considered largely a time of ovarian quiescence. Serial ultrasonographic examination of the ovary in lactating women showed that the ovarian activity can begin, and several different patterns of follicular activity can occur before full fertile cyclicity becomes established. In some of these transitory stages, concentrations of total urinary estrogens and pregnanediol were increased, which caused cervical mucus patterns that are consistent with fertility. This was confusing for the lactating women who were using natural family planning methods to avoid a pregnancy. These results suggest the limitation of the mucus symptom in predicting a truly fertile cycle in the lactating woman.

The authors gratefully acknowledge the technical staff responsible for conducting ultrasonographic studies, hormone analysis, and data analysis: Kate Hudson, Joanne Holmes, Gillian Barker, Dr. Meg Smith, and Cindy Visness. Finally, our deep gratitude goes to Mrs. Anne McCarthy, who conducted the follow-up visits, and to the mothers who persevered in attending the Ultrasound Department for Ovarian Scanning over months and years.

Ovulation method use during breastfeeding: Is there increased risk of unplanned pregnancy?

Miriam H. Labbok, MD, MPH,^a Rebecca Y. Stallings, MHS,^b Farida Shah, MSc,^b Alfredo Pérez, MD,^c Hanna Klaus, MD,^a Mark Jacobson, MD, MPH,^b and Theresa Muruthi^e

Washington, D.C., Baltimore, Maryland, Santiago, Chile, Nyahururu, Kenya, and Arusha, Tanzania

Data from two prospective studies of the ovulation method were used to assess pregnancy rates and users' fertility-related behaviors among breastfeeding women. The rate of unplanned pregnancy was <1% during the first 6 months of lactational amenorrhea. However, the unplanned pregnancy rate was elevated among breastfeeders during the months after menses return compared with the pregnancy rate during nonlactating cycles. Rates were also elevated at the time when infant feeding supplementation was started. This increase in unplanned pregnancies was not directly attributable to nonadherence to the ovulation method rules; there was some indication that adherence to the rules actually may be increased during those months. Therefore, special emphasis on both the need for improved breastfeeding support to delay menses return and the increased potential for method failure among new users during this period of time should be incorporated into ovulation method training and support programs. (AM J OBSTET GYNECOL 1991;165:2031-6.)

Data from two prospective studies of the ovulation method (OM) were analyzed to assess pregnancy occurrence and related behaviors. The first was carried out in Nyahururu, Kenya. It was originally designed to assess the cost-effectiveness of OM and the impact of different intensities of training. The second was in Santiago, Chile, and was designed to study the efficacy of the OM during breastfeeding. The purpose of this article is to illustrate that (1) special times during breastfeeding, especially the months of lactational menses and time after the commencement of supplemental infant feedings, can be associated with increased preg-

nancy rates among OM users; (2) this phenomenon is not a result of laxity in method adherence on the part of the users; and (3) because breastfeeding is the norm in most areas of the world, and because international support for optimal breastfeeding practices will be increasing, it is necessary for OM trainers to be aware of the above facts and be skilled in the appropriate introduction and use of OM during breastfeeding.

Methods: Nyahururu

Details of the Nyahururu study have been presented elsewhere. This was an operations research study in which training protocols of different lengths were introduced and client data and charts were collected monthly from the time the couple attended the first teaching session to learn the method. The data were sent to the Johns Hopkins University for analysis.

Data included basic information about each woman, such as teaching method, age, and other background information, along with data for charted cycles. Cycle is defined as the period from first day of one menstrual period to the first day of the subsequent period. In nonmenstruating women, the cycle is the period of time charted between interviews, approximately 30 days. After exclusion of women who were sterilized (seven), unable to maintain charts (nine), or not trying to avoid pregnancy, the data file contained information for 521 natural family planning (NFP) users from 42 sites near Nyahururu who entered the project between September 1983 and November 1986. Data collection for this project was carefully supervised by the project director and was generally of good quality, although there were some problems maintaining uniformity in the data collection procedures over time.

Analyses included frequencies and means of major variables, as well as descriptive presentation. For this article the major analyses included the development of cumulative 12-month life tables with standard errors, logistic regression with use of the PHGLM package, which takes into account censored data, and descriptive tables. All statements of statistical significance are based on p < 0.05 in a two-tailed test of significance.

Results: Nyahururu

Among the predominantly rural and Catholic population of Nyahururu, the unplanned cumulative pregnancy rate was about 22 per 100 women at 12 cycles/mo. Fifty-nine percent were lactating and 47% were amenorrheic at entry. Because a lower rate of pregnancy had been expected among lactating women, the population was divided into those who were lactating at program entry and those who were not. The pregnancy rate among women who were lactating at entry and continued lactating through a first menses was 18.5%, but that among women who were not lactating at entry was only 14.1% (Table I). This is not statistically significantly different. Although numbers were small, the highest rate of pregnancy was among those who were lactating at entry and never menstruated. This trend was unexpected; a lower rate of pregnancy had been expected among lactating women.

Maternal age and stated pregnancy intention had no influence on the pregnancy rate after lactational status was controlled. Among lactating women younger than 30 years of age, the pregnancy rate at 12 months was 19.6% whereas among the older lactating women the pregnancy rate was 17.0%, which is not significantly different. Among the nonlactating women the 12-month pregnancy rates were 13.3% for the younger women and 14.5% for the older women, also not statistically significant (Table I).

Pregnancy rates after menses return were also assessed. Entry into this life table occurred at the first recorded menstrual cycle and was controlled for both lactational status and maternal age (Table II). The pregnancy rate for the 12 cycles after menses return among women whose menses began during lactation was 36.5% for the younger women and 32.9% for the older women. The rate among menstruating, nonlactating women from the time of the first recorded menses was approximately 13% for all age groups. Within lactation status, no significant differences were seen, but the difference between the pregnancy rates of cycling lactating women and cycling nonlactating women was highly significant (p < 0.0001).

Table III. Nyahururu study: Percentage of cycles with intercourse occurring within each phase of cycle, by lactation status and by whether unplanned pregnancy occurred

	U	nplanned pregna	псу		No pregnancy	•
	Prefertile	Fertile	Postfertile	Prefertile	Fertile	Postfertile
Lactating	59.7	5.4	28.7	65.8	5.8	15.8
Nonlactating	55.4	18.5	59.8	39.1	7.4	60.2

Occurrence of intercourse during fertile days was much higher in cycles of nonlactating women who become pregnant compared with those who did not become pregnant. However, intercourse activity was not elevated in cycles of lactating women who become pregnant.

The pregnancy rates for the first 3 to 6 months after menses return were extraordinarily high among lactating women, approximately 12% in the younger women and 7% in the older women. This age group difference also may be caused in part by a difference in intensity of breastfeeding practiced by the different age cohorts, because it disappears by the end of the first year of lactational menses. Furthermore, by logistic regression analysis, the major single predictive variable for unplanned pregnancy was lactational status at entry (p < 0.0007). The only other variable predictive of unplanned pregnancy was entry into the study relatively early postpartum (p < 0.035).

The next series of analyses was concerned with whether the women who had unplanned pregnancy during lactational menses were ignoring the rules of the method. An analysis of the percentage of women who had intercourse during the prefertile, fertile, and postfertile periods was undertaken. These results were then separated according to whether the women had had an unplanned pregnancy (Table III). Among lactating women there was little difference in timing of intercourse between those who did and did not have an unplanned pregnancy. The percentage who reported intercourse during the fertile period was 5.4% for those with an unplanned pregnancy, and 5.8% among those who did not have a pregnancy. There was a higher rate of recorded postfertile-period intercourse (28.7%) among those who had an unplanned pregnancy compared with those who did not (15.8%).

Any breastfeeding and amenorrhea	2.1	2.2

^{*}Categories significantly different at p < 0.05 level within grouping.

Among nonlactating women, however, there was a difference in the percentage reporting intercourse during the fertile days. Intercourse during the fertile days was recorded in only 7.4% of the cycles among those who did not become pregnant compared with 18.5% among those who had an unplanned pregnancy, a significant difference. The nonlactating women who had an unplanned pregnancy also reported a higher rate of intercourse in the prefertile period (55.4% vs 39.1%).

An additional analysis addressed the same issue by time postpartum. Among lactating women, there were no major trends over time except for some decrease in

total abstinence and some increase in intercourse during prefertile "dry" days. Both those who became pregnant and those who did not appear to have been adhering to the rules similarly. Among those not lactating, however, there were notable differences between those who became pregnant and those who did not. Those who became pregnant tended to have intercourse during the fertile period much more often and earlier postpartum, with relatively more intercourse in the prefertile period and relatively less intercourse in the postfertile period. The trends in total abstinence, however, were similar between lactating women and nonlactating women who became pregnant and between lactating women and nonlactating women and nonlactating women who did not become pregnant.

A third analysis on this issue assessed whether these differences might result from large differences in the number of days falling in each part of the cycle. The only finding was a slightly longer average cycle length among those who became pregnant (29 vs 28 days), which would not appear to account for the significant differences seen above.

From this we may conclude that the couples in which the woman was lactating on entry into the OM program were more likely to have an unplanned pregnancy even though they were not ignoring the rules. Rather, on average, the lactating women adhered to the rules more closely than the nonlactating, practicing abstinence on fertile days significantly more frequently.

Methods: Santiago

In Santiago a prospective study was conducted that included primarily lactating women. The data collected

on 378 births and postpartum OM use are reported elsewhere.² These women had a 12-month cumulative pregnancy rate of 12%.

The analyses for this article were derived primarily from the records of the 110 women for whom data were available on signs and symptoms and occurrence of intercourse by day postpartum. Data were also available on feeding (full breastfeeding, partial breastfeeding, or no breastfeeding), mother's and father's age, education, religion, number of living children, reason for accepting NFP, attitude toward an unplanned pregnancy, marital status, and previous abortion and pregnancy occurrence.

Cross tabulations were used to assess several parameters to compare usefulness of sensation versus observation for the signs and symptoms record. Student's t tests, linear modeling, and proportional hazards modeling were used to examine those variables associated with onset of a fertile episode. Tabulation and logistic regressions were used to assess variables associated with occurrence of intercourse on a prohibited day. Reported sensation signs and observation signs were compared to see whether either seemed to be associated with the identification of an appropriately timed fertile episode. Although sensation signs do occur earlier than observation in lactating women, neither was notably better at identifying a fertile period before the first menses. Sensation indicators were selected to be used for all further analyses. For these analyses, OM signs and symptoms of fertility occurring 8 to 20 days before

an episode of vaginal bleeding are considered to reflect fecundability.

Results: Santiago

Life table analyses were used to explore the relationships between menstrual status, breastfeeding status, and pregnancy rates (Table IV). As expected, the cumulative pregnancy rate at 6 months was significantly lower among the amenorrheic women (1.2%) than among those whose menses had resumed (8.2%). The pattern of lactation gave a "dose response"; the more intensive the breastfeeding, the lower the occurrence of unplanned pregnancy (p < 0.05). This trend was also seen among amenorrheic women, but here the trend was not significant.

After menses returned, breastfeeding continued to have a depressive effect on unplanned pregnancy for the first 3 months. After that time, however, lactational menses again was associated with an unexpected high level of unplanned pregnancy (Table V).

Three variables were shown in a time-dependent proportional hazards model to be significant and highly predictive of fertility return. Consistent with results of other studies, the return of menses was associated with the return of fertility ($\beta = 1.6045$). The initiation of supplemental feeding, or the switch from exclusive to partial breastfeeding, also proved to be associated with fertility ($\beta = 1.6475$). A third variable, weaning or cessation of any lactation, also was associated with the return of fertility with similar strength ($\beta = 1.6527$).

Table VI confirms these findings in a linear model for association with fertility return. This model used slightly different variables (return of menses and completed weaning two cycles previously). Another variable identified with the fertility return is the occurrence of a peak symptom.

The return to fertility predicted by the proportional hazards and linear models is directly reflected in the pregnancy rates, with the important exception of higher fertility seen after 3 months of lactational menses. Because this phenomenon is not readily explained by the physiology of lactation, and because all

women in the subset of 110 were also using the mucus method to space their births, the coital behavior of this population, as recorded on the OM charts, was studied to assess whether the adherence to rules accounted for this difference in fertility. Among these breastfeeding women we found that 4% reported coital activity during menses, 10.5% on dry days, 0.7% on the day after intercourse, 0.8% on the fertile days, 0.2% on peak days, 10.5% on infertile days, and 9.8% on the spotting days (Table VII). Of interest is that this rate of intercourse, averaging about three acts per month, is lower than was found with practitioners of the lactational amenorrhea method (LAM) who were of approximately the same age and parity.3

The percentage of days that abstinence was required by the OM rules as time passed postpartum, as well as coital behavior, was calculated (Table VIII). In the first 3 months, abstinence was necessary on 20% of the days; in the second 3 months postpartum it was required on about one third of the days. In the sixth to ninth month postpartum, intercourse was prohibited on 41% of the days and later increased to 45% to 47% of the days. Correspondingly, 2% to 4% of abstinence days reportedly included coitus throughout the first postpartum year, and the percent of "free" days with a coital act increased throughout the year, beginning at about 14% in the first 3 months and increasing from 20% to 22%. After the end of the first year postpartum, the percentage of abstinence days with reported intercourse increased to 10% and the percentage of free days with reported intercourse increased to 31%.

Using LAM would have greatly decreased the number of abstinence days for these couples. It would have allowed all days up to 6 months to be free days, providing the women were fully breastfeeding their infants and were amenorrheic. Analysis of the unplanned pregnancy data from those who were breastfeeding showed that 67% of the pregnancies were user related and 25% were method related, and among those not breastfeeding 85% were user related and 15% method related.⁴

The pregnancies among lactating women primarily occurred after menses returned in the sixth to ninth month postpartum. However, the logistic regression model for adherence to rules showed that this particular variable was associated with significant adherence to the rules (Table IX).

Although some of these analyses do not have numbers large enough to achieve statistical significance, there is an apparent consistency across all of the presented analyses to illustrate that the users were attempting to adhere to the method during lactational menses but were, nonetheless, becoming pregnant.

Conclusion

There is an increased risk of unplanned pregnancy in newly trained OM users during lactational menses, and this increase does not seem to be a result of lack of adherence to the rules. In light of the global emphasis on breastfeeding and our knowledge of fertility suppression during full lactational amenorrhea, and in light of the international interest in NFP acceptability and efficacy, attention must be paid to the particular issues of support for the client during the interface between NFP and breastfeeding. We hope that future research will shed light on improved NFP method use and teaching methods for the postpartum months, as well as on improving teaching methods for the LAM/OM interface for the later months, so that couples can reliably depend on the OM during these crucial months.

We thank Family Health International, especially Kathy Kennedy, for her ongoing support and editing guidance.

Efficacy of the symptothermal method of natural family planning in lactating women after the return of menses

Michael Zinaman, MD, and Wilma Stevenson, BAb Washington, D.C.

This study was designed to determine the efficacy of the symptothermal method of natural family planning during lactation. Although the method appears to give a reasonable reflection of fertility potential over time, it overlaps with the profound influence of lactation in both ovulation suppression and the delay of luteal phase adequacy. Further analysis is planned to attempt to identify those particular mucus signs and symptoms that are helpful during the transition from lactational amenorrhea to normal cycling. (AM J OBSTET GYNECOL 1991;165:2037-9.)

Key words: Natural family planning, symptothermal method, lactation, urinary luteinizing hormone

The purpose of this study was to determine the efficacy of the symptothermal method of natural family planning (NFP) in lactating women, particularly during the first three cycles after the cessation of lactation-induced amenorrhea, in a pilot study of 25 women.

Methods

A total of 28 women were screened for inclusion in the study and 25 completed the study. During the course of the study, women recorded their daily breast-feeding episodes, introduction of supplements, and their daily NFP signs and symptoms. In this case the records included basal body temperature and in all cases, bleeding or spotting episodes. The protocol was standardized so that all subjects would be recording the same set of mucus symptoms on a daily basis. All women remained in the study for an average of 13 months; the range was 9 to 17 months. All women were discontinued from the study after they had had three apparent ovulatory cycles as determined by the urinary excretion of estrone-3-glucuronide, luteinizing hormone (LH), and pregnanediol-3-glucuronide.

Results

Delineation of the day of ovulation by means of basal body temperature was compared with delineation of the day of ovulation by means of urinary LH excretion. The results among these 25 lactating women were as follows.

6/0/34247

For the first cycle, the shift in temperature occurred a mean of 4 days from the day of urinary LH peak +1. The proximity of the "LH peak +1" day and the basal body temperature shift improved in the subsequent three cycles to within a mean of 1 day of the urinary LH peak +1. This suggests that the initial rise in basal body temperature during the first cycle, which in 23 of 25 cases preceded the first menstruation, is considerably less accurate than in subsequent cycles and has a high false-positive rate (Fig. 1).

The length of the luteal phase in the 25 women showed a significant change over the four cycles during which they were monitored. The length was determined by the day of LH peak +1 to the day of commencement of menstruation. If the first cycle occurred within the first 6 months of lactation, the luteal phase was insufficient as determined by its length (<10 days). Only 20% of cycles, which occurred in the first 6 months postpartum had luteal phase lengths of 10 days or greater. If the first cycle occurred after 6 months of lactation, this number increased to 60% of those who had luteal sufficiency during their first cycle (Fig. 2).

To determine the first possible return to fertility, the data were analyzed relative to the postpartum day on which the first cycle occurred. Normalized to the day of the first LH peak that followed by a pregnanediol rise, 25% had the first cycle less than 200 days postpartum. An additional 25% had their first cycle between 200 and 300 days postpartum, 35% between 301 and 400 days postpartum, and 15% greater than 400 days postpartum. An analysis to relate these findings to the patterns of breastfeeding is presently underway (Fig. 3).

Comment

The use of the symptothermal method in lactating women appears to give reasonable information to these

Volume 165 Number 6, Part 2

couples about their fertility potential. In spite of this, the influence of lactation is obviously quite profound for the first 6 months. A preliminary analysis reveals that the first cycle is frequently accompanied by an insufficient luteal phase, especially if it occurs in the first 6 months postpartum. This supports other published findings, which document lower rates of first-cycle adequacy before 6 months among lactating women.^{1,2}

In addition, the accuracy of basal body temperature

appears to be limited during the same first cycle. Further analysis of this data set should help us to understand whether there are particular mucus signs and symptoms that will help women during this early transition from amenorrhea to normal cycles.

Santiago Breastfeeding Promotion Program: Preliminary results of an intervention study

Alfredo Pérez, MD and Veronica Valdés, MD

Santiago, Chile

A prospective intervention study was undertaken in Santiago, Chile, to assess the impact of a breastfeeding promotion program and the acceptance and use of the lactational amenorrhea method for natural child spacing. The intervention study significantly increased the duration of exclusive breastfeeding and amenorrhea. In addition, the use of the lactational amenorrhea method proved highly efficacious, with an unplanned pregnancy rate of less than 0.5% by 6-month cumulative life table. Total family planning coverage at 6 months was increased in the intervention group. (AM J OBSTET GYNECOL 1991;165:2039-44.)

Key words: Lactational amenorrhea method, breastfeeding, breastfeeding promotion

The benefits of breastfeeding for both mother and child have been clearly demonstrated. Nonetheless, in the past few years in some developing countries, a decrease in the length of the breastfeeding period and changes in breastfeeding patterns have been observed. This has encouraged the development of breastfeeding promotion and support programs either hospital-based or at the community level, with diverse results. 10-14

The purpose of this intervention study (Breastfeeding Promotion Program) of urban women of Santiago, Chile, was twofold: to design and test the impact of a simple hospital-based model, which would modify

breastfeeding practices, and at the same time to design a program that could be easily replicated in other developing countries.

Moreover, the program was designed with the intention of not only increasing the number of mothers interested in breastfeeding and extending the duration of exclusive breastfeeding, but also verifying that the impact of amenorrhea caused by exclusive breastfeeding on women's fertility can be accepted and used efficaciously to delay conception. 15-17

Material and method

The Breastfeeding Promotion Program included the training of the health team, activities in the prenatal outpatient clinic, activities on the maternity ward, and an open lactation clinic.¹⁷

After gathering data on a control group of 313 mother-child pairs who followed the usual postpartum and infant feeding routines of the University Hospital of the Pontificia Universidad Católica de Chile, the Breastfeeding Promotion Program was initiated. A group of 422 mother-child pairs of urban, lower-middle class whose pregnancy, delivery, and postpartum

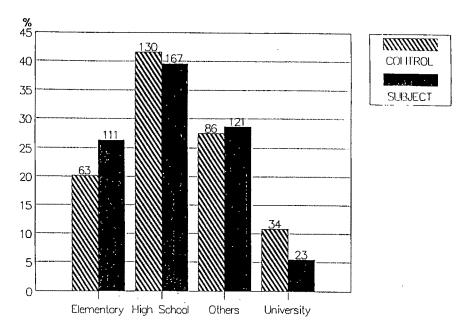

Fig. 1. Women's educational level: study group (422 cases) and control group (313 cases). (Illustration provided by Georgetown University.)

care were delivered at the hospital, were then recruited to serve as the study population.

Recruitment criteria for both groups included healthy women with no previous history of infertility; a normal breast examination; stable couple; work situation compatible with 6 months of exclusive breastfeeding; and term vaginal delivery, with a healthy child whose birthweight was over 2500 gm. The mother-child pairs in the control and study groups were followed up every 30 days until completing 180 days postpartum. The first follow-up was performed between 7 and 14 days postpartum, and this was considered the point of study entry.

During each follow-up visit, mothers were thoroughly interviewed about their breastfeeding habits, the introduction of supplementary feeding, the presence of vaginal bleeding, the frequency of sexual intercourse, and the use of family planning methods. In each follow-up the baby had a complete physical examination, and the breastfeeding technique was observed and supervised; whenever necessary, the mother was given a gynecologic examination. The infant feeding record kept by the mother for the past 24 hours before the interview was analyzed; this included the number and duration of breastfeedings during the day and night, type of supplementary feeding, time schedule, and quantity.

The mothers in the study group were requested to accept the criteria of the lactational amenorrhea method (LAM) as their child-spacing method and were advised not to use other contraceptive methods during full lactation and amenorrhea in the first 6 months postpartum. 16, 17 The analysis of the behavior of the

study group in relation to the control group included the following statistical procedures: univariate analysis with standard errors, Student t test for comparison of means, Fisher's test for 2×2 tables, and χ^2 test for tables of greater categories. In addition, life table analyses were used to assess time-related events. In the first 6 months of the program, only 3.8% of the control group and 3.0% of the study group were lost to follow-up.

Results

Population characteristics. The characteristics of the study and control groups were similar: the mothers' ages ranged from 18 to 39 years (mean, 26.8 ± 4.7 years in the control group and 27.1 ± 5.0 years in the study group), and parity was between 1 and 5 (1.7 ± 0.8) in the control group and 2.0 ± 0.8 in the study group). The weight gain of the mothers in both groups during pregnancy showed no significant difference (13.9 ± 4.5) in the control group, and 13.4 ± 4.3 in the study group). The educational level of the control group mothers was slightly higher than that of the study group (p < 0.019); the control group included fewer mothers with an elementary education and more mothers with university studies (Fig. 1). There was no difference in the fathers' educational level.

Onset of breastfeeding. On average, breastfeeding was initiated at 6.7 ± 8.0 hours postpartum in the control group and at 2.8 ± 2.3 hours in the study group. These findings were significantly different (p < 0.001).

Supplementary feeding of newborns in the mater-

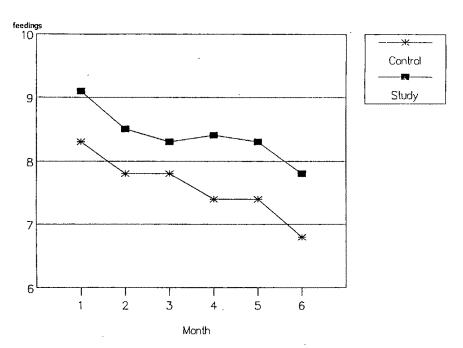

Fig. 2. Mean number of breastfeedings per day during the first 6 months postpartum.

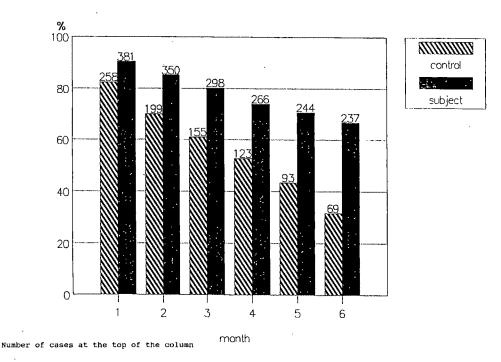

Fig. 3. Percentage of women exclusively breastfeeding and ammenorrheic during the first 6 months postpartum. (Illustration provided by Georgetown University.)

nity ward. Fifty-three percent of newborn infants from the control group received supplementary feeding during their stay in the maternity ward compared with only 19% of newborn infants in the study group (p < 0.001).

Breastfeeding frequency. Fig. 2 shows the mean number of breastfeeding episodes in 24 hours in the control and study groups during the first 6 months postpartum; the study group consistently had a higher number of feedings per day.

Status at the end of the sixth postpartum month. Of the control group mothers, 31.6% completed 180 postpartum days of exclusive breastfeeding compared with 66.8% of the study group mothers. At 180 days postpartum, 73 (23.3%) infants from the control group and

NFP, Natural family planning.

45 (10.7%) from the study group had been fully weaned from breastfeeding.

Forty-five percent of mothers from the control group and 64% from the study group remained amenorrheic for 180 postpartum days or more, whereas 69 (22.0%) mothers in the control group and 237 (56.2%) from the study group completed 180 postpartum days of exclusive breastfeeding and remained amenorrheic (Fig. 3).

Of the control group, 10.2% completed 180 postpartum days exclusively breastfeeding and amenorrheic, whereas 52.4% of the study group did so without the use of another form of family planning. The study group mothers had actively chosen to use amenorrhea as their method because of exclusive breastfeeding.

At the end of the sixth month, 66 (22%) mothers in the control group did not use any family planning method. Including LAM, the total active coverage increased from 78% in the control group to 91% in the study population. The selection of family planning methods in the control group was as follows: intrauterine devices, 21%; hormonal, 42%; barrier methods, 8%; natural family planning, 7%; and without family planning, 22%. It should be noted that 10% of those who were protected by the parameters of LAM did not

report it as a method. Method use among the study group was LAM, 52%; intrauterine devices, 15%; hormonal, 13%; barrier methods, 9%; natural family planning, 3%; and without contraception, 9% (Fig. 4).

Pregnancies. Five pregnancies were registered in the control group in the first 180 postpartum days, and four pregnancies were registered in the study group during the same period. The month that pregnancy occurred, the presence of menses, the state of breast-feeding, and the use of family planning when pregnancy occurred are presented in Table I.

Combining all mothers in both the control and study groups who completed 180 postpartum days in amenorrhea, who exclusively breastfed, who used no family planning methods other than LAM, and who were sexually active, only one pregnancy occurred. This yielded a 6-month cumulative life table pregnancy rate for LAM of 0.4% (Table II).

Growth curve (weight/age) of male and female infants exclusively breastfed for 6 months. Fig. 5 shows the growth curve of exclusively breastfed male and female infants in the study group during their first 6 months of life compared with the growth curve of the National Child Health studies. It may be seen that exclusively breastfed infants performed comparably.

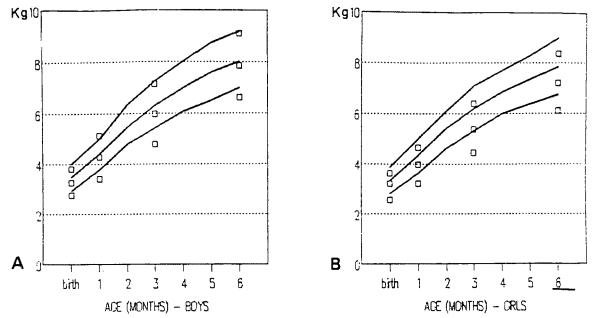

Fig. 5. Comparisons between National Child Health Studies growth curve (0) and weight/age of male (A) and female (B) infants in the study group exclusively breastfed during the first 6 months postpartum. (Illustration provided by Georgetown University.)

Comment

The Breastfeeding Promotion Program for urban women of Santiago, Chile, appears to have had a positive impact on several paramaters related to breastfeeding. Changes occurred not only in the behavior of the study population but also among the health team in charge of the mothers and infants, as well as in the policies of the Departments of Obstetrics and Pediatrics. This statement is supported by the fact that in the study group, the period between delivery and first suckling was significantly reduced. Thus the average time postpartum to the initiation of breastfeeding in the study group was 2.8 hours, whereas 6.7 hours elapsed after delivery in the control group. Another piece of supporting evidence is that the number of newborn infants who received supplementary feeding during their stay in the maternity ward was significantly re-

Perhaps the most encouraging result of the Breastfeeding Promotion Program was the significant increase in the number of mothers in the study group who completed the sixth month postpartum exclusively or fully breastfeeding compared with control group mothers; only about 32% of the latter group was exclusively breastfeeding at 180 days postpartum, whereas 67% of the study group was exclusively breastfeeding at that time. This trend is reinforced by the data on completed weaning; at 6 months postpartum, 23% of the control group mothers had already weaned their baby, whereas only 10% of the mothers in the study group had weaned before 180 days postpartum.

In light of the Innocenti Declaration, which led to the statement accepted by the World Summit on Children, this breastfeeding promotion program contributed substantially toward optimal breastfeeding in this population. When analyzing the growth curves of the infants during the first 6 months of life, it can be seen that infants in the study group, who were exclusively breastfed during the first 6 months, showed a growth curve (50th percentile) that was actually higher than

that for international standards derived from the National Child Health Studies of the United States especially in female infants.

The number who completed 180 postpartum days in amenorrhea was also significantly higher in the study group (64.5%) compared with the control group (45%), as was the number who completed 180 postpartum days both amenorrheic and exclusively breastfeeding—56% in the study group and only 22% in the control group. This result reinforces the possibility that a program that encourages and promotes breastfeeding may have a profound impact on the duration of the infertile period. The intervention more than doubled the percentage of women who were naturally protected against an unplanned pregnancy, thereby reconfirming that full breastfeeding amenorrhea confers more than 98% protection against pregnancy during the first 6 months postpartum.15

The decrease in the use of alternative family planning methods during the first 6 months postpartum in the study group was more than overcome by the percentage accepting the natural breastfeeding/amenorrhea approach. LAM is acceptable, and breastfeeding promotion can play an important role in cost savings both in the hospital and by saving family planning resources within health services. 18 The 99.6% pregnancy protection rate demonstrated in this intervention for women in exclusive breastfeeding amenorrhea without family planning during the first 6 months postpartum corroborates the previous work in this area and the Bellagio Consensus. 15, 16, 19-22

In conclusion, breastfeeding promotion programs can have a positive impact on hospital policies and the health of women and children. If these programs include the fertility aspects (LAM), they can also contribute to child-spacing coverage, presenting an additional highly efficacious and natural option for women to consider.

Discussion and recommendations

Discussion included the advantages of the incorporation of the lactation amenorrhea method (LAM) into natural family planning (NFP):

- It is simpler for couples newly interested in NFP.
 While they are using LAM, they have a chance to
 learn NFP in a more relaxed fashion than if they
 would have to apply all aspects of NFP at once.
- 2. It would delay the moment when it is necessary to start observing and charting the signs of NFP until the baby is older and the mother is less tired.
- 3. It would prevent the couple from observing unnecessary abstinence because of slight changes in fertility signs during the early postpartum months when in fact those changes have little significance.
- It is believed that the acceptability of NFP during breastfeeding would be increased if it were preceded by LAM, for the reasons mentioned previously.

Recommendations included:

- Improved, standardized nomenclature, definitions, and educational messages are needed, particularly with regard to potential fertility (fecundity).
- 2. Several research priorities were noted:
 - What are the implications of the Bellagio recommendations for different groups and countries? After 6 months?
 - What is the "within woman" variation in the duration of LAM and its potential fertility impact (i.e., can the duration of LAM and the return of potential fertility after one pregnancy

6/0/34251

- be used to predict the times of these events in a successive pregnancy)?
- What are the correlations between indices of returning potential fertility? Can additional markers be identified?
- Can methods be devised to reduce the falsepositive and false-negative signals of existing methods?
- Can the physiology of LAM and breastfeeding through the first year be better understood?
- What are the patterns of feeding within full breastfeeding that have the greatest impact on fertility suppression?
- What is the influence of nutritional factors and other clinical symptoms on returning fertility and the detection of existing clinical and biochemical indices?
- What is the role of pediatricians and other health workers in counseling women?
- 3. Education may be necessary to address the concerns of NFP providers. Some providers are reluctant to accept the 2% risk of pregnancy stated in Bellagio Consensus criteria; primarily, they may not realize that early pregnancies among their breastfeeding clients occur because these women are not within LAM criteria (fully breastfeeding, <6 months postpartum, and amenorrheic). A multiphase approach was suggested, which included presentations of scientific background of LAM to medical committees, training of trainers, curriculum development, and refresher training for teachers. Supervisory follow-up to support new activities could follow.

SESSION IV. NATURAL FAMILY PLANNING USE-EFFECTIVENESS AND CONTINUATION

Robert T. Kambic, Chair Suzanne Parenteau-Carreau, Rapporteur

Natural family planning use-effectiveness and continuation

Robert T. Kambic, MSH

Baltimore, Maryland

Numerous studies have been conducted to assess the use-effectiveness of natural family planning. However, because of imprecise definitions of terms, these studies show noncomparable results. Special effort is required to study natural family planning use-effectiveness by the same criteria as other family planning methods. (AM J OBSTET GYNECOL 1991;165:2046-8.)

Key words: Natural family planning, use-effectiveness, pregnancy rates

Any method of fertility control, natural family planning (NFP) included, has two major purposes; at the personal level it enables couples to have the number of children they choose, and at the aggregate level it moderates population growth so that the community, the common good, will benefit. To help couples plan their families, service programs must be able to communicate accurate information on how and how well a method can be used. Civil and medical authorities need to have confidence that the family planning methods they recommend will help their populace achieve better health.

Thus science has a responsibility to measure effectiveness, continuation, and other family planning evaluation parameters as accurately and reliably as possible. This has been done in large part for medical contraception but is only beginning for NFP.

Studying NFP use-effectiveness

There is a 10- to 15-year time lag between NFP evaluation and evaluation of other family planning methods. Tietze¹ cites 10 studies on tubal sterilization, 36 studies on oral contraceptives, and other studies on the intrauterine device and barrier methods, virtually all published in the mid to late 1960s. Many of these were studies of thousands of women. Tietze also cites two basal body temperature studies published in 1967 and 1968 with 17,500 and 5000 cycles, respectively. In contrast, the first large trial of the symptothermal method was the Rice study, which was first reported in 1977 with 1022 women²; the first large trial of the ovulation method, the World Health Organization study, published initial results in 1981.³ This time lag benefits NFP

6/0/34195

to the extent that it adapts the refined methodologies of family planning evaluation for its own use. It has hindered NFP because a lack of knowledge about the efficacy has up to now relegated NFP to a subordinate role in family planning.

When adapting family planning evaluation methodology for NFP application, knowledge about data collection, results generalization, statistical approaches, and developed-developing country comparisons can be transferred directly to NFP. However, there are other issues that only NFP research can resolve, e.g., the study population in NFP has to be precisely defined. Does a client enter the study at registration, when she is taught, when she begins to chart, or after she has charted for 1, 2, or more months? Definition of the study population is especially important to determine early dropout rates. Another example is the study unit: is it the woman or the couple? The woman charts her symptoms but assuming monogamy, both partners abstain. When considering pregnancies occurring in NFP users, there are two approaches: the accepted practice is to define a pregnancy according to the stated family planning intention of the client before a pregnancy occurs. An alternative practice recommended by some is to classify pregnancies according to the intercourse record of the client during the fertile time of the cycle in which the pregnancy occurred. If intercourse during the fertile time is always indicative of a desire for pregnancies, then unplanned pregnancies are virtually eliminated.

In summarizing the 1986 Ottawa conference of the International Federation for Family Life promotion, Dr. Paul Gross, who paraphrased Dr. Ronald Gray said

Professor Gray emphasized the dangers of defining these terms in NFP services in a way that does not allow easy comparison with the rates derived from services using other family planning methods. Because NFP will be judged by

use-effectiveness and continuation 2047

Table I. A decade of NFP effectiveness studies ranked by pregnancy rate; life table rates are cumulative net pregnancies at 1 year or 13 cycles per 100 women. (For definitions of life table and Pearl rates, see Labbok et al., which immediately follows.)

such comparisons, those dangers outweigh the advantages and leave the NFP movement open to unnecessary criticism.⁴

Of special interest are the simplified methods. It is not that people cannot use the standard NFP methods, but the simplified methods are less technical, easier to learn, and in some cases are literally being developed "in the field" by independent users (users not associated with an NFP program). Sociologists know that new, helpful knowledge will spread throughout a community by diffusion, that is, neighbors telling neighbors. NFP simplified methods may be currently undergoing diffusion and are important to a substantial proportion of couples in countries such as Mauritius, the Philippines, and Indonesia.

Communicating results

The most precise scientific results in the world are not helpful unless we use them. As Carl Djerassi⁵ pointed out, a crisis exists in the field of contraceptive development that has provided an opportunity for a fresh look at NFP. To take advantage of this opportunity, the results of effectiveness studies in NFP should be provided to those who will make use of them.

Table I lists NFP life table and Pearl index effectiveness studies reported during the past decade. Because of the methodology problems in measuring use-effectiveness, the data are not strictly comparable. (For a detailed discussion of the problems of comparing life table rates among studies and methodology problems in family planning evaluation, see Trussell and Kost⁶).

However, an examination of the life table rates in Table I is informative in several ways. There is a factor of about 10 between the lowest reported pregnancy rate of 2.5 and the highest rate of 27.9. Both are ovulation method studies. The median is 13.1.

Of the life table studies with pregnancy rates higher than the median, most were completed early in the 1980s. Of the studies with pregnancy rates lower than the median, all but one were completed after 1988. This suggests that throughout the 1980s, NFP programs improved their service, which enabled clients to achieve better effectiveness. This trend should be monitored.

When the Pearl index studies are included in the meta-analysis, we see a diverse group of countries at different levels of development where NFP services are sufficiently established to undertake a study of effectiveness rates. These countries are favorable sites for continued research and program improvement.

The articles presented in this section represent examples both of effectiveness studies and factors that impact on NFP effectiveness and continuation. They discuss a variety of approaches to these issues, reveal past methodologic errors, and provide information on NFP efficacy.

Efficacy studies in natural family planning: Issues and management implications illustrated with data from five studies

Miriam H. Labbok, MD, MPH, Hanna Klaus, MD, and Alfredo Perez, MD

Washington, D.C., Bethesda, Maryland, and Santiago, Chile

Studies of method effectiveness must be carefully assessed for comparability of findings. Several parameters are identified that are important in the assurance of comparable results. This article discusses these issues with the use of data from previously published studies and emphasizes the management implications of use-effectiveness data. (AM J OBSTET GYNECOL 1991;165:2048-51.)

Key words: Natural family planning, use-effectiveness, ovulation method

Many family planning programs, whether natural family planning (NFP) or others, attempt to gather data to assess the effectiveness of the method(s) they are using. This is a useful effort not only for increasing understanding of the potential impact of the program but also for helping in management decisions. However, these data are not always easily gathered, and the manner of data collection can profoundly affect the outcomes and their comparability. This article discusses issues in use-effectiveness analysis and the application

Table I. Study design and sample

_	N	Median age (yr)	Entry
Chile: prospective, post-	419	28	Mo 1
Bangladesh: retrospective	201	26	Mo 4
Kenya I: retrospective	151	30	Autonomous
Korea: retrospective	168	32	Mo 1
Kenya II: prospective, interval	512	30	Mo 1

of such analyses to management decisions with examples from five studies.¹⁻⁴

Issues in data analysis

Contraceptive effectiveness is measured both clinically, for a "theoretical efficacy," and in actual usage, for "use efficacy." Clinical trials prospectively measure the efficacy of a method, whereas in-use measurements may be based on population surveys. The failure rate or the unplanned pregnancy rate is expressed as the number of pregnancies per 100 women or womanyears of exposure. This may be calculated as a Pearl index whereby the number of unplanned pregnancies is divided by the number of months of exposure and multiplied by 1200. The failure rate may also be calculated by the cumulative life table technique, an actuarial approach that is most often used to evaluate the first 12 months of use. Life tables permit the assessment of method efficacy over time and statistical comparison, but the Pearl index has the advantage of being easier to calculate.

A major problem in measurement of use-effectiveness is the accurate recording of the number of unplanned pregnancies that occur. Pregnancy reporting may suffer both from reporting bias and from loss to follow-up. These can be called "numerator problems" in that they affect the numerator in the calculations.

"Denominator problems" in NFP efficacy calculations can be illustrated with the data that is presented in Table I. These problems result from self-selection into the method, bias of recall, different times of entry into the studies, and, possibly from unreported concurrent use of other methods. As shown in Table I, clinical trials may have considerable variability among these parameters, and this may create difficulty in comparison of findings. For example, the Chilean study included a large population of postpartum women who were using the ovulation method (OM) and recording data each day; study entry was within 1 month of method acceptance. Studies in Bangladesh, Kenya I, and Korea were what might be called "prospective-retrospective;" that is, the data were gathered prospectively from time of entry but only as part of regular records, which were not designed to assure complete follow-up, but analyzed retrospectively.

Table II. Cumulative life table unplanned pregnancy rates and standard errors per 100 women who used the method for spacing or limiting

	9 Mo (%)	12 Mo (%)
Chile		
All women	6.9(1.4)	10.7 (1.8)
No breastfeeding	14.2 (3.9)	16.8 (4.0)
Any breastfeeding	4.5 (1.7)	
Bangladesh	10.1 (2.1)	14.9 (2.6)
Kenya I	10.4 (2.8)	10.4 (2.8)
Korea	9.5(2.4)	13.4 (2.8)
Kenya II	•	
All women	14 (1.7)	18 (1.9)
No breastfeeding	13 (2.6)	15 (2.8)
Any breastfeeding	14 (2.3)	19 (2.9)

In addition, it may be seen that the median age of the participants varied greatly and that the number of months of method use that were already completed at the time when data gathering began varied considerably. For example, the group in Kenya I did not enter the study until the acceptors had become autonomous users of the OM, whereas the group in Kenya II, which was a prospective study, entered the study whenever the couple first came to learn NFP. Another important issue is the comparability of the populations in each study. Age, for example, is known to affect fertility, and the clients who self-selected themselves into these programs were of different median ages.

When the data problems described above (different study designs, time of entry, self-selection and self-reporting, and consistency of method use and follow-up) are taken into account, the differences in the results that are presented in Table II are not surprising. For example, in an examination of only the three studies that followed a similar protocol (Bangladesh, Kenya I, and Korea), the lowest unplanned pregnancy rate is recorded when entry into the study was late, after autonomy was achieved. The center with the youngest population showed the highest unplanned pregnancy rate. The studies in Chile and Kenya II allow us to look at the breastfeeding versus nonbreastfeeding populations. When study entry is immediately after delivery (Chile), breastfeeding is protective against unplanned pregnancy, but when study entry occurs at any time during the interbirth interval, breastfeeding apparently is associated with an increase in unplanned preg-

Unplanned pregnancy rates were calculated only for those who used the method to avoid conception. Among studies that are presented herein, unplanned pregnancy rates varied from 10% to 19% with 95% confidence intervals that encompass a range of 4.8% to 25% (Table II). Life table rates for studies in the United

States and other developed regions range from 16 to 27.5.6 Three prospective studies in developing countries and a World Health Organization (WHO) collaborative study found rates between 5 and 24.7 Early postpartum breastfeeders who use the OM seem to benefit from the fertility-reducing side effect of lactation, whereas the late breastfeeders seem to have more difficulty in using the OM to avoid pregnancy. It should also be noted that use-effectiveness for other forms of family planning in similar settings is not well known. It is not unreasonable to assume that these rates may be comparable to those of other methods under these conditions and in these settings.

At a meeting on cost-effectiveness, which was sponsored by the Institute for International Studies in Natural Family Planning in 1988, an alternative plan to address unplanned pregnancy rates was suggested. It was suggested that the percent of clients who achieve adequate spacing or who achieve their stated goal might be a better indicator of success. This approach to effectiveness assessment has three advantages: it is a personalized indicator that reflects the couples' plans, it may be easier to assess, and it would give a manager excellent information over time. The major disadvantage is that this approach disallows comparisons between methods and among programs, an activity that is often necessary for funding support and method promotion.

Use of efficacy data in management decisions

A better understanding of efficacy data and how it is gathered can lead to improved management decision making. Life tables can give us an understanding of many issues, especially when multiple-decrement life tables are used. In the Chilean study, 12-month life tables indicate that about 12% of the women dropped out to become pregnant, 12% experienced an unplanned pregnancy, and 7% changed to another method for a total discontinuation rate of about 32%. The remaining 68% would represent the total cumu-

lative continuation rate. By similar analysis the three countries (Bangladesh, Kenya I, and Korea) had approximately 67% continuation and Kenya II, in part because of the higher unplanned pregnancy rate, had a continuation rate of 50%. The continuation rate is an indicator of the percent of acceptors who are still using NFP at the end of 1 year. In assessment of a program, low continuation rates should alert the manager to consider program modification. By assessing the contribution of each element to the discontinuation (pregnancy, switching, drop-out), the manager can be alerted to the most appropriate intervention approach.

Another area of analysis that is helpful in management is an exploration of the unplanned pregnancies by category. Table III illustrates the distribution of the unplanned pregnancies in these five studies by several categories. This first breakdown is by method- and user-related categories. In user-related categories, two options were considered: (1) when the rules are not understood (whether this is due to problems with the teacher or the student) and (2) when the rules are understood but are not following the cycle of conception. In addition, there is an unknown or undetermined category.

An example of how examination of these categories may help a manager is seen in the study in Chile. This is the study with the highest percentage of breastfeeders; there is also a higher method-related failure rate. The manager who is seeking an explanation would find that the majority of these user-related pregnancies occurred during lactation but after return of menses and therefore after return of fertility. The manager could thus address program resources to this issue.⁹

The most common contributor to the user-related category is when knowledgeable users do not follow the rules of the ovulation method. However, in Korea many of the failures were attributed to misunderstanding of the rules as a result of teaching problems. The high number of unplanned pregnancies that were categorized as unknowns in the Korea and Bangladesh studies

may be the result of cultural hesitance to record the occurrence of sexual relations. This information allows the manager of the program to reassess teaching methods, learner knowledge, and behavioral difficulties. An intervention may target teacher's education or client support to assist in understanding or following the rules of NFP.

Studies of effectiveness allow program managers to judge their program in comparison with studies that are reported in the literature. Comparisons can be made in terms of those variables that are frequently associated with unplanned pregnancy (e.g., maternal youth), and progress can be monitored within that category over time. Data in the five studies that are discussed in this article seem to show that some variables that have been generally accepted as associated with unplanned pregnancy lose that association when other variables are properly controlled.^{1, 3}

For example, we find that when lactation status is adequately controlled, the difference in pregnancy rates between spacers and limiters virtually disappears. It should be noted, however, that the clients' stated receptivity to an unplanned pregnancy is associated with the occurrence of unplanned pregnancy; this stated receptivity occurred both among spacers and limiters. Therefore it is possible that this is a much better indicator of the need for special counseling than is a statement about spacing versus limiting.

Conclusions

It is clear that all of the above information has implications for management. Therefore the study of efficacy is not simply for academic purposes but to improve management. Those who develop management information systems should consider including measures of NFP efficacy that will allow the program manager to make adjustments that are necessary to improve the impact of the program.

The data that were used to illustrate ovulation method use-effectiveness issues are from studies coauthored with Dr. Alfredo Perez, Dr. Hanna Klaus, Ms. Teresa Muruthi, Mrs. Farida Shah, and Dr. Mark Jacobson. We thank Dianne Barker and Ms. Rebecca Stallings for research assistance.

Effectiveness and acceptability of the symptothermal method of natural family planning in Germany

Petra Frank-Herrmann, MD,^a Günter Freundl, MD,^a Siegfried Baur, MD,^b Michael Bremme, MD,^a Gerd K. Döring, MD,^b Erhard A.J. Godehardt, PhD,^c and Ursula Sottong, MD^d

Düsseldorf, Munich, and Bonn, Germany

Throughout Germany, 851 women who were instructed in natural family planning participated in a prospective study. Of these, 255 women with 3174 cycles used only natural family planning for family planning and 274 women with 3995 cycles occasionally used barrier methods in the fertile phase. For natural family planning—only users, the Pearl rate for unplanned pregnancy was 2.3 and for mixed-method users 2.1. Most pregnancies resulted from unprotected intercourse during the fertile phase, and the use of barrier methods does not reduce risk-taking. (AM J OBSTET GYNECOL 1991;165:2052-4.)

Key words: Natural family planning, effectiveness, symptothermal method

In 1985, a representative public opinion poll showed that in Germany about 4% of the women between 15 and 45 years of age use a natural method of family planning (NFP). The main reason German couples adopt NFP is dissatisfaction with other contraceptive methods or fear of their side effects.

In a prospective study supported by the German Ministry for Youth, Family, Women and Health,¹ we have studied the use-effectiveness and the acceptability of the symptothermal method of NFP, the sexual behavior of the users, and the proportion of women or couples who use NFP only ("NFP users") or who use barrier methods in the fertile phase ("mixed-methods users"). Furthermore, we also wanted to know how many couples avoiding pregnancy have intercourse in the fertile phase without any contraceptive protection. The study, begun in 1984, is in progress and is a joint project of the University of Düsseldorf and the Arbeitsgruppe NFP, Bonn.

Material and methods

The study participants and, when possible, their partners have been instructed in small groups by about 500 NFP teachers. They were instructed in the symptothermal method, (STM) which mainly uses self-observation of the cervical mucus and basal body temperature to define the beginning and the end of the fertile phase of the cycle.² To avoid pregnancy, no intercourse should take place in the fertile phase.

From Frauenklinik Städtisches Krankenhaus, Düsseldorf-Benrath,^a the University of Munich,^b the Biometric Unit of the Cardiovascular Surgical Department, University of Düsseldorf,^c and Arbeitsgruppe NFP, Bonn.

Table I. Sexual behavior in fertile phase (N = 506)

	%
NFP only	
No intercourse in fertile phase	12.5
Occasional unprotected intercourse in fertile	34.2
phase	
Mixed method	
Occasional protected intercourse	11.3
Occasional protected and unprotected intercourse	42.1

The woman's observations are entered on a specially developed cycle chart. The woman also records sexual behavior including protected and unprotected intercourse and other forms of genital contact. In addition, the client states on each chart whether or not she wants to become pregnant in the next cycle. Pregnancies are classified as "intended" or "unintended" on the basis of the statements made before conception. To enter the effectiveness study, the participants must be between 20 and 45 years of age and have a cycle length of 25 to 35 days.

All women who request NFP are taught, including women with irregular cycles, women who have discontinued oral contraceptives, and women who are premenopausal, are breastfeeding, have had an abortion, and are trying to conceive. Within the prospective study, a woman may first use NFP in the postpartum situation, then may be in the use-effectiveness study for some cycles, and then try to achieve a pregnancy.

A self-developed computer program serves for data collection, statistical evaluation, supervision and organization of the NFP teachers, and administration. With use of this program, interim results can be reviewed at any time.

Table II. Significant differences between consistent and inconsistent users

	Consistent users $(n = 120)$ (%)	Inconsistent users (n = 386) (%)
Working or training/housewife	69/31	53/47*
Unmarried/married	44/56	26/74*
No child/one or more children	62/38	46/54*

There were no significant differences in age, educational level, completed family size (spacer/limiter), unintended pregnancy before study entry, experience with other family planning methods, or religion. *p < 0.05.

Results

Altogether there are 851 women with 12,765 cycles in the study. Of these, 506 women with a total of 6891 cycles met the conditions of the effectiveness study. Of these, 241 women with 3007 cycles used only NFP for family planning and 265 women with 3884 cycles occasionally used barrier methods, mainly the condom, in the fertile phase.

Women with a cycle length of <25 or >35 days are often excluded from effectiveness studies because of the assumption that they have reduced fertility. However, we found that women with short cycles have fully adequate cycles with early ovulations and sufficiently long luteal phases (high-temperature phase of 10 days or longer). Only cycle lengths of <22 days are often connected with signs of subfertility. The high fertility of women with short cycles has been shown by the relatively high number of unintended pregnancies among them, and we therefore included them in the use-effectiveness study. Therefore, for the NFP-only users there were two more unintended pregnancies in 167 cycles and for mixed-method users one more unintended pregnancy in 111 cycles. The Pearl Index for NFP-only users (with a cycle length of 22 to 35 days) was 2.3 and for mixed-methods users was 2.1.

The educational level of NFP clients is higher than in the general population. Fifty-nine percent have attended grammar school or the university. One reason for this circumstance is that information on NFP is obtained through books or by means of special educational institutions; little information can be obtained via the media or physicians. The participants are comparatively young, with 67% between 19 and 29 years old, and almost half of them are childless. Seventy-three percent of the women want more children in the future and are spacing. Eighteen percent have completed their family size and are limiting. There are no significant differences between NFP-only users and mixed-methods users. The lost-to-follow-up rate is 2.6%, and dropouts because of dissatisfaction and problems with NFP are 7.1%.

In the use-effectiveness study for NFP-only users, we found four unintended pregnancies in 3007 cycles, which results in a Pearl rate of 1.6. For mixed-methods users, the Pearl Index was 1.9 with six unintended pregnancies in 3884 cycles.

Of the 13 unintended pregnancies, three were method failures. The other 10 pregnancies occurred in cycles in which unprotected intercourse took place during the fertile phase. This means that those who at times used barrier methods also had unprotected intercourse during the fertile phase. Many user-related pregnancies occur because couples, though refraining from intercourse in the highly fertile phase, risk unprotected intercourse just at the beginning of the fertile phase believing "nothing will happen this time."

Among NFP-only users there were two method failures. In both cases the coitus responsible for the conception took place on the fifth cycle day, once 7 days before temperature rise and in the other case 5 days before temperature rise. The third method failure occurred in the mixed-methods group, when there was no intercourse in the fertile phase.

Table I shows how couples behaved in the fertile phase. Groups 1 and 3 were the consistent users whereas groups 2 and 4 were the risk-taking groups that occasionally had unprotected intercourse during the fertile phase. It is surprising that those who sometimes used barrier methods still had unprotected intercourse in the fertile phase. Thus, the use of barrier methods does not reduce additional risk-taking.

Table II compares the consistent users (groups 1 and 3 of Table I) with the risk-taking group (groups 2 and 4 of Table I). This table shows that women who were working or in training outside the home, women who were unmarried, and women with no children were more likely to be consistent users (p < 0.05). Conversely, women who were housewives, were married, or had children were more likely to take risks (p < 0.05). Consistent users may have been more motivated to avoid pregnancy.

Comment

Many prospective studies deal with effectiveness of NFP in Europe, in the United States, and in a number of developing countries.3-9 Our study adds information about sexual behavior in the fertile phase of the cycle. In the current study, the unplanned pregnancy

rate was low and was comparable to that with use of the intrauterine contraceptive device. The other studies show unplanned pregnancy rates that differ widely from each other and range from very good to very poor because of methodologic or cultural factors. We found that Germany NFP users frequently took risks and had unprotected intercourse in the fertile phase. They mostly broke the rules at the beginning of the fertile phase when the risk of pregnancy was rather low.

Summarizing, the use-effectiveness of the examined symptothermal method is very good. It is true that users do not always behave consistently. If, however, they have unprotected intercourse during the fertile phase, they do so at the beginning of the fertile phase knowing they are taking a risk. The low drop-out rate shows good acceptance. About half of the women or couples who are taught sometimes use barrier methods in the fertile phase.

Further analysis of contraceptive failure of the ovulation method

James Trussell, PhD, and Laurence Grummer-Strawn, PhD

Princeton, New Jersey

Reanalysis of data on the ovulation method of natural family planning collected by the World Health Organization yields the following conclusions. The method is effective during perfect (correct and consistent) use, with a first-year probability of failure of 3.4%. However, it is extremely unforgiving of imperfect use, with a first-year probability of failure of 84.2% if the method is not used correctly. During the initial year, 87% of the cycles were characterized by perfect use. Nevertheless, the 13% of cycles characterized by imperfect use had a tremendous impact on the overall failure rate. During the first year of typical use, 22.5% of the women in the clinical trial became accidentally pregnant. (AM J OBSTET GYNECOL 1991;165:2054-9.)

Key words: Natural family planning, ovulation method, use-effectiveness

The standard procedure for calculating separate failure rates caused by method and user error is logically flawed and produces estimates that are biased down-

From the Office of Population Research, Princeton University. This analysis was supported by a subcontract from Georgetown University under a prime grant (DPE-3040-A-00-5064-00) from the Agency for International Development.

The views expressed by the authors do not necessarily reflect those of Georgetown University or the Agency for International Development. Reprint requests: James Trussell, PhD, Princeton University, Notestein Hall, 21 Prospect Ave., Princeton, NJ 08544-2091. 6/0/34197

ward, with the extent of bias unknown. In a previous paper, we provided correctly calculated estimates of method and user efficacy for the ovulation method (OM). Using data collected in a clinical trial conducted by The World Health Organization (WHO), We analyzed failure rates separately for perfect use (when the method is used correctly and consistently) and imperfect use. Probabilities of a contraceptive failure during the first year after successful completion of a teaching phase are 3.1% during perfect use and 86.4% during imperfect use. We concluded that if used perfectly, OM is very effective in preventing pregnancy. However, it

is extremely unforgiving of imperfect use, especially breaking rules forbidding intercourse during the fertile period or during times of stress. Breaking these most serious OM rules entails a 27% risk of pregnancy per cycle.

Our previous analysis of OM efficacy was based on the 13-cycle effectiveness phase of the WHO study. The effectiveness phase was preceded by a teaching phase that lasted from three to six cycles. The purpose of the present study is to determine whether analysis of efficacy during the teaching phase can enhance understanding of the probabilities of failure during perfect and imperfect use and of the pregnancy risks of particular forms of imperfect use. We also combine the data from the teaching and effectiveness phases to compute the probability of failure during the actual first year of use of OM so that the result will be comparable with the results for other methods without a separate teaching phase. Finally, we explore further the relationship between the probabilities of failure during perfect and imperfect use and the probability of failure during typical use and the meaning of this formal relationship for counseling clients.

Data

WHO invited five centers with experience in teaching OM to participate in a clinical trial. The centers were located in Auckland (New Zealand), Bangalore (India), Dublin (Ireland), Manila (Philippines), and San Miguel (El Salvador). Participants in the trial were required to be less than 39 years old, not to be lactating, to have a history of menstrual cycles of between 23 and 35 days, to have had at least 1 live birth (or term stillbirth) within the preceding 5 years in the present union, to be cohabiting, not to have used hormonal contraception for at least three cycles before admission, not to have used OM previously, to agree not to use any other method of contraception during the effectiveness phase of the study, and to be an informed volunteer willing to keep the necessary records.

A total of 869 women were admitted to the teaching phase of three to six cycles. Of these, 765 (88%) successfully completed the teaching phase, and 725 entered the effectiveness phase (with the remaining 40 patients withdrawing for a variety of reasons, including desire for pregnancy, dissatisfaction with the method, and moving away). The OM rules, which are described in greater detail in Table I of our previous paper, forbid intercourse during menses, on alternative early "dry" days before the start of the fertile period (to minimize confusion between seminal fluid and cervical mucus), during the fertile period itself, and during periods of stress. The fertile period begins with the onset of mucus secretion, peaks on the last day on which "fertile" mucus (resembling raw egg-white) is recog-

nized, and ends on the evening of the fourth day past the peak day. Intercourse is forbidden on roughly half the days in each cycle. The first cycle of the teaching phase had a completely different rule—intercourse was forbidden altogether—with important implications for the analysis of efficacy of OM (discussed below).

Separate data collection forms were used for each menstrual cycle, with each subject recording fertile days, days of bleeding, and days of intercourse. From the chart and a monthly meeting during which the teacher carefully questioned the subject, the teacher transcribed selected cycle details onto a paper form and judged compliance, comprehension, and attitude. Totals of 2701 cycles were recorded for the 869 women who entered the teaching phase and 7514 cycles for the 725 women who entered the effectivness phase. Copies of all forms were checked for consistency and completeness at WHO headquarters, where an analysis file in machine-readable format was created. This analysis file was generously provided to us by Dr. P. F. A. Van Look at WHO.

The forms for the teaching and effectiveness phases differ in several important ways that hamper analysis of the combined data. First, as previously mentioned, the initial cycle in the teaching phase had an additional rule that forbade intercourse. Second, there were several additional categories of imperfect use on the teaching phase forms that did not exist on the effectiveness phase forms, including improper charting, intercourse on the peak day, and intercourse around the time of a second peak. Categories common to forms in both phases were intercourse during times of stress, intercourse on consecutive dry days, intercourse on mucus/wet days, intercourse within 3 days after peak, genital contact on wet days, intercourse during bleeding/spotting, and use of other methods. Thus it is not clear how uniquely to map categories during the teaching phase into categories during the effectiveness phase. Of particular concern is the fact that improper charting usually precludes even knowing which real rules were broken.

Finally, the form for the teaching phase recorded only whether or not coitus occurred during the cycle and not how many times; the form for the effectiveness phase recorded total acts of intercourse, but it is clear that the number of acts was underreported. Women were asked to report all acts of intercourse and required to record the last act before the onset of the fecund period, all acts during the fecund period, the first act after the end of the fecund period, and whether all acts during the cycle were reported. It is clear that not all acts of intercourse during the fecund period were reported. Conception rates per cycle day are much higher in the WHO trial than in other studies, and the WHO investigators themselves concluded that under

reporting of intercourse occurred during the fecund phase.⁵ Furthermore, frequency of intercourse (even among those who reported that they recorded all acts) was unrelated to the probability of failure during perfect use and imperfect use. Unless the risk per exposure of an event occurring is zero, then it logically follows that the more times one is exposed, the greater should be the probability that the event will occur.

In our analyses, we discarded 560 cycles in the teaching phase and 30 cycles in the effectiveness phase during which women reported that no intercourse had occurred. We retained 46 cycles in the teaching phase and 156 cycles in the effectiveness phase for which insufficient information was available to determine whether intercourse had occurred; in short, we assumed intercourse occurred unless there was direct evidence to the contrary. One might object that those who do not have intercourse in a cycle are nevertheless perfect users of OM. However, women simply are not exposed to the risk of contraceptive failure unless they have intercourse, so that periods characterized by no exposure to risk of pregnancy should be removed. 8-10

Moreover, all qualitative results would be identical regardless of the inclusion or exclusion of these cases, and the quantitative impact of including the cycles with insufficient information to determine whether coitus had occurred or excluding the cycles during which intercourse did not occur is trivial. The total number of cycles included in the analyses is 2141 in the teaching phase and 7484 in the effectiveness phase. Finally, we were forced to impute perfect/imperfect use in a small number of cases in which data were missing; only for one cycle in which pregnancy occurred (in the effectiveness phase) did we have to impute perfect/imperfect use.

Results

How to treat the first cycle is a vexing issue, because intercourse was forbidden in that cycle. Nevertheless, 397 of 869 couples (46%) definitely disobeyed this rule, eight of whom (2.0%) became pregnant. In 16 cases there is no evidence whatsoever whether the couples had intercourse, and in two cases whether the couples had intercourse was left blank, but additional information indicated that no rules were broken. In subsequent analyses involving the initial cycle, these 16 cases were coded as having intercourse (and thus disobeying the rules in cycle 1), and the two cases were coded as not having intercourse (and thus obeying the rules) to be consistent with our general imputation procedure that we eliminated cycles only if there was evidence that no coitus occurred.

By definition, those who used OM perfectly during the first cycle did not have intercourse and thus were not exposed to the risk of pregnancy. As stated above, cycles in which couples are not exposed to risk should be removed from the analysis of contraceptive efficacy. Nevertheless, if we count all 869 cycles of exposure in the first cycle of the teaching phase (regardless of whether intercourse occurred), then the life table probability of failure in the initial year (cycles 1 to 13) of use is 22.0%. If we skip the first cycle altogether, the first-year (cycles 2 to 14) probability of failure is 21.9%. If we count only those initial cycles in which intercourse occurred, the initial-year probability of failure rises to 22.8%.

Life table probabilities of failure during the first year (cycles I to 13) are 84.1% during imperfect use and 3.2% during perfect use; if the initial teaching cycle is excluded, these probabilities rise slightly, to 85.0% and 3.4%, respectively. Hence the life table probability of failure in the initial year of use is fairly insensitive to the treatment of the initial cycle of the teaching phase. For this reason and because rules are so fundamentally different, we discard this initial cycle in all subsequent analyses.

During cycles 2 to 6 of the teaching phase, there were 37 pregnancies in the 1728 cycles in which intercourse occurred, or a 2.1% failure rate per cycle. Three pregnancies occurred during 1386 cycles of perfect use (failure rate = 0.22%) and 34 occurred pregnancies during 342 cycles of imperfect use (failure rate = 9.9%). The failure rate per cycle during perfect use (0.22%) was nearly identical to and not statistically different from the failure rate during perfect use in the effectiveness phase (0.24%). This result conforms to the hypothesis that we articulated in our previous paper, because we reasoned that during perfect use, only biologic fecundity and frequency of intercourse should affect the propensity to fail and that these factors would not differ much between the teaching and effectiveness phases.

In contrast, the failure rate per cycle during imperfect use (9.9%) was significantly lower than the failure rate during imperfect use in the effectiveness phase (14.1%). Two factors could account for this difference: (1) On average the rules couples break in the teaching phase might be expected to be less serious than the rules broken in the effectiveness phase, and (2) on average the number of times couples break rules per imperfect-use cycle might be expected to be lower in the teaching than in the effectiveness phase. We expect that both factors would operate because couples are likely to be more careful until they gain experience with OM; both could result from less frequent intercourse during the teaching phase. Couples break rules more often in the teaching phase—20% of cycles were characterized by imperfect use compared with only 11% in the effectiveness phase-probably because of an imperfect understanding of OM during the initial cycles of the teaching phase.

Table I. Pearl index failure rates by type of rule-breaking during the teaching phase

^{*}Calculated as $(1 - [1 - P^{18}]$, where P is the probability per cycle (number of pregnancies per number of cycles). Note that this annual probability is purely notional, since the teaching phase lasted 6 months at most.

Probabilities of failure per cycle and per year are shown in Table I for overall use, perfect use, imperfect use, and specific types of imperfect use during the teaching phase. The probabilities presented in Table I are based on Pearl index and not life table calculations. For these data, differences in cumulative failure rates from the two methods are nearly identical, because duration-specific rates do not vary much. Specific types of imperfect use are shown in two panels. The upper panel pertains to cycles in which a specific rule was broken regardless of whether other rules were also broken; the lower panel pertains to those cycles in which the specific rule listed was the only rule broken.

The upper panel of Table I indicates that having intercourse on mucus/wet days, within 3 days after the peak, during situations of stress, on the peak day, or around a second peak are particularly risky, with an implied annual probability of failure exceeding 90%. Having intercourse during cycles that were mischarted or during bleeding/spotting or having genital contract during wet days entails a high risk, with an annual probability of failure exceeding 50%. Having intercourse on consecutive early days has the lowest risk (16.6% would fail in the first year). However, it is possible that breaking a specific rule only appears to be risky because it is broken in combination with other rules that do entail great risk when broken. The only way to

answer this question is to examine cycles in which only one rule was broken.

The lower panel of Table I confirms that having intercourse within 3 days after the peak, on the peak day, or around a second peak is indeed risky; breaking any of these rules entails at least a 95% chance of pregnancy within a year. However, the risk of pregnancy from intercourse on mucus/wet days, during bleeding/spotting, or during cycles that were mischarted is substantially lower than would be indicated by the upper panel; when these rules are broken (in the upper panel), more serious rules seem to be broken as well.

It is difficult to compare the risks entailed by breaking specific rules in the teaching phase with the corresponding risks in the effectiveness phase because imperfect use was coded differently in the two phases. Specifically, the last three categories shown in Table I do not exist for the effectiveness phase. Our previous analysis of the effectiveness phase indicated that rules with the most serious consequences when broken were those forbidding intercourse on mucus/wet days, within 3 days after the peak, and during situations of stress. Breaking the rules forbidding intercourse during bleeding/spotting and genital contact on wet days entailed the smallest risk. The risk from intercourse on consecutive early days was intermediate.

The results in Table I are in general agreement with

[†]Annual 95% confidence interval computed from cycle confidence interval based on exact binomial. Cycle confidence interval has 2.5% area in each tail except when p = 0.0 or p = 1.0, in which cases the cycle confidence interval has 5% area in one tail.

[‡]Annual 95% confidence interval computed from cycle confidence interval based on normal approximation. Cycle confidence interval has 2.5% area in each tail.

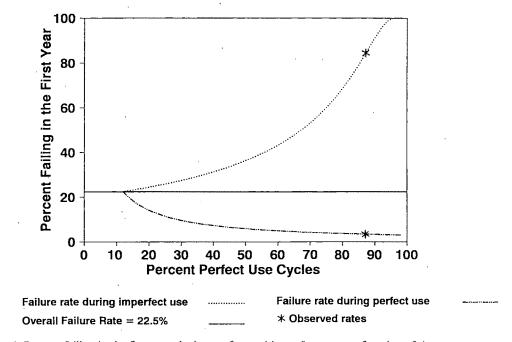

Fig. 1. Percent failing in the first year during perfect and imperfect use as a function of the extent of perfect use.

our prior findings with the following two exceptions: (1) intercourse on consecutive early days has a lower risk in the teaching phase, and (2) intercourse on mucus/wet days has a far lower risk in the teaching phase. The risk of pregnancy from intercourse on mucus/wet days in the teaching phase, when that is the only rule broken, seems implausibly low. Because this particular risk is so low, because we cannot match the imperfect use categories for the two phases, and because we suspect that specific types of imperfect use would be more precisely identified in the effectiveness phase when the couples had acquired better charting skills, we conclude that our prior results for the effectiveness phase more accurately reflect the true risks of breaking particular rules.

Implications of misreporting

Classification of exposure cycles as perfect or imperfect clearly requires accurate reporting of behaviors. It is plausible that imperfect use would be underreported, given the understandable human tendency not to emphasize one's failings. Underreporting seems far less likely in those cycles in which pregnancy did occur, because the investigators examined the circumstances surrounding all pregnancies especially carefully. If so, then our perfect-use failure rates are too low, but our imperfect-use rates are too high. In this section we explore more formally the consequences of misreporting.

In the first year of use (cycles 2 to 14) of OM during

the WHO trial, 159 pregnancies occurred in 8209 cycles. This 1.94% failure rate per cycle translates into 22.5% of couples failing in the first year of use. There were 19 pregnancies in 7150 perfect-use cycles (3.4% of couples failing in the first year) and 140 pregnancies in 1059 imperfect-use cycles (84.2% failing in the first year). The typical per cycle failure rate is the weighted average of the per cycle failure rates for perfect and imperfect use: $f_i = \alpha f_p + (1 - \alpha) f_i$, where f_i , f_p , and f_i are per cycle failure rates for typical, perfect, and imperfect use, respectively, and α is the proportion of perfect-use cycles. Note that α can be interpreted as an index of how easy the method is to use correctly and consistently; the smaller is α , the more difficult it is to use the method perfectly. We regard these four pieces of information (f_i , f_p , f_i , and α), only three of which are independent, as necessary for a couple to make a truly informed choice of a contraceptive method.

If we assume that pregnancies are properly classified as occurring during perfect or imperfect use, although perfect or imperfect use in cycles in which pregnancy did not occur might be misreported, then we allow for the possibility that the failure rates that we have computed for perfect and imperfect use are incorrect. Nevertheless, the following equation holds for the OM data: $f_1 = 0.0194 = (n/8209) (19/n) + ([8209 - n]/8209) (140/[8209 - n])$, where n is the true number of perfect use cycles, 19/n is the true failure rate during perfect use, and 140/(8209 - n) is the true failure rate

during imperfect use. We are led to the inescapable fact that if the failure rate during imperfect use is lower than the rate reported, then the failure rate during perfect use must be higher than that reported.

Fig. 1 shows the annual probabilities of failure implied by changing n from its reported value of 7150 ($\alpha = 0.871$) to a low of 981 ($\alpha = 0.119$) that would result in $f_p = f_t$ to a high of 8069 ($\alpha = 0.983$) that would result if all cycles were perfect-use cycles except the 140 in which pregnancy occurred during imperfect use. In constructing this figure, we assume that the failure rate during perfect use cannot exceed the failure rate during imperfect use. These results imply that at one extreme OM is very forgiving of imperfect use but has very low efficacy in preventing pregnancy and is very difficult to use perfectly.

At the other extreme, OM has high efficacy in preventing pregnancy if used perfectly but is extremely unforgiving of imperfect use and very easy to use perfectly. Our previous conclusion, based on the reports of perfect and imperfect use in the data, falls near the latter extreme. We have concluded that OM is extremely unforgiving of imperfect use and moderately difficult to use perfectly ($\alpha = 0.871$, thus OM is used imperfectly in 13% of cycles). If one wished to argue that the method is in fact more forgiving, because our estimate of imperfect-use efficacy is biased upward by misreporting of rule-breaking, then it must also be true that the method when used perfectly has lower efficacy and that OM is more difficult to use perfectly.

In conclusion rule-breaking during the teaching phase of the OM trial was more common than rulebreaking during the effectiveness phase. One would expect this finding given that understanding of the method and charting skills improve with experience. Fortunately, it seems that the specific rules broken in the teaching phase seem to have consequences on average that are less serious than rules broken in the effectiveness phase. Two findings seem particularly relevant to counseling. First, the rule forbidding intercourse during the first teaching cycle was disregarded by nearly half the couples in the trial, among whom 2% became pregnant. Given this fact, it would seem advisable to emphasize during the initial teaching session that couples not have intercourse before charting skills are established. Further, couples should be counseled to use an adjunct (nonhormonal) method if they cannot adhere to this rule. Second, couples should be advised that OM is quite effective at preventing pregnancy when used perfectly but that it is extremely unforgiving of imperfect use.

Factors related to autonomy and discontinuation of use of natural family planning for women in Liberia and Zambia

Robert T. Kambic, MSH, and Ronald H. Gray, MD

Baltimore, Maryland

From 1983 to 1988, natural family planning programs were conducted in Liberia and Zambia. In Liberia 1055 and in Zambia 2709 women used natural family planning to avoid pregnancy. These users could become pregnant, discontinue use of the method, or become autonomous users. Women who changed intention did not stop use of natural family planning and were not treated as discontinuations. In a multivariate analysis, client's age, breastfeeding status, employment, urban/rural residence, time of registration in the program, and visit intensity were significantly associated with the outcomes. The most consistent association was that women who entered the programs in the later time periods were more likely to become autonomous users and less likely to discontinue use of the method or to experience an accidental pregnancy. (AM J OBSTET GYNECOL 1991;165:2060-2.)

Key words: Natural family planning, autonomous users, unplanned pregnancy. Liberia, Zambia

From 1983 to 1988, natural family planning (NFP) demonstration programs were conducted in Liberia and Zambia. The overall evaluation of these programs has been reported in a companion volume to this publication. Here the focus is on factors that are associated with autonomous use, discontinuation of use, and unplanned pregnancy among women who wanted to avoid pregnancy in Liberia (1055) and in Zambia (2709).

Methods

At registration, data were collected on socioeconomic characteristics, reproductive history, breastfeeding status, and family planning intention. Those who charted for 1 month were considered to be "learning" users from the first day charted. At 3-month intervals a follow-up form was completed to record any change in family planning intention and number of client/teacher contacts during the interval. Unplanned pregnancies were defined as conceptions to women who stated that they were using NFP to avoid pregnancy during the follow-up interval in which the pregnancy occurred. There were a total of 39 pregnancies in Liberia and

changed their family planning intention see Kambic and Martin.2)

A learning user was classified as autonomous if she had learned the method and could chart her signs without further instruction. Autonomous clients were followed to ascertain their discontinuations and pregnancies. There were 612 autonomous users in Liberia and 955 in Zambia.

To examine categorical differences in discontinuation, life tables were calculated for 11 different socioeconomic, program, and client variables: (1) family planning intention (spacing vs limiting), (2) age, (3) parity, (4) education, (5) religion, (6) occupation, (7) place of residence, (8) breastfeeding status, (9) NFP method (i.e., either symptothermal or ovulation method), (10) intensity of teacher/client visits (three categories-low, medium, high), and (11) period of registration during the program (divided into the first, second, and third 18 months of the program).

A Cox proportional hazards model, which is a linear multivariate statistical model, was used to predict which of the above variables were significantly associated with autonomy, discontinuation, and unplanned pregnancy. The dependent variable is survival time for an event; for example time from the first day charged up to pregnancy, discontinuation, or autonomy. The independent variables are factors that are hypothesized to be related to the survival time until the event. The exponent of the coefficient of each independent variable provides

an estimate of the relative risk of the event with respect to a baseline group; controls for the other variables in the model were applied. The Cox models were run with the SAS PHGLM procedure. The results of the Cox model agreed with the results of stratified life table analyses.

Results

Of the above variables, parity, education, and family planning intention were not found to be significant in either country in any model. These variables are not in the reduced models that are shown in Tables I, II, and III. In each table the reference group is indicated by an asterisk and has a relative risk of 1.0. The comparison groups have a risk for the outcome event that is calculated with reference to the reference group.

Table I shows the relative risk for becoming an autonomous user. In both countries, women who were breastfeeding and women who were housewives were significantly less likely to become autonomous users. Also, in both programs women who registered later in the program were more likely to become autonomous users, with the increase being significant in Liberia, and women who received more visits per month were more likely to become autonomous (significantly so in Zambia).

Table II shows the relative risk for discontinuation. Women who registered later in both programs were less likely to discontinue, and the lower risk is significant

Am J Obstet Gynecol

in both countries. Visit intensity was significantly related to discontinuation of use in Zambia, and women who had more visits were less likely to discontinue. In Liberia urban women had a much higher risk (7.50, p < 0.001) than rural women of discontinuing. In Zambia women who were older than 35 and women who were breastfeeding were significantly less likely to discontinue use of the method. These associations were not seen in Liberia.

Table III shows the relative risk for unplanned pregnancy. In Zambia breastfeeding women have reduced risk (relative risk = 0.28, p < .001) of becoming pregnant compared with nonbreastfeeding women. In Liberia urban women had a 13.74 (p < 0.001) elevated risk of becoming pregnant compared with rural women. Also in Liberia women with a medium intensity of visits were 2.28 (p < 0.05) times more likely to become pregnant than women with the lowest intensity of visits.

Comment

Although several factors are associated with a higher probability of progression to autonomy or lower likelihood of discontinuation or pregnancy, no factors were found to be consistently associated with all measures of NFP use in both programs. The most consistent association was that women who entered the programs in the later time periods were more likely to become autonomous users and less likely to discontinue use of the method or to experience an accidental pregnancy. This might suggest that program improvements over time led to better NFP use. However, because of truncation, the results that relate to the time of registration should be interpreted with caution.

With the exception of unplanned pregnancy in Liberia, the results for visit intensity are as expected; more visits per time period resulted in a higher progression

to autonomy and less discontinuation and pregnancy. This suggests that program inputs can beneficially affect NFP use. In Liberia women with a medium visit intensity were more likely to become pregnant. It is possible that women who have unplanned pregnancies are more likely to become pregnant in the early months of NFP use when visits occur more often. However, since visits decline with time during learning, if women do not become pregnant, they may, on the average, have fewer visits per time period than women who have unplanned pregnancies and discontinued earlier.

Breastfeeding was significantly associated with better outcomes in Zambia but not in Liberia. This may relate to the differences in breastfeeding practices between the two countries. In Liberia urban women were at much higher risk for unplanned pregnancy (13.74) and discontinuation (7.50) but showed no increased risk for becoming autonomous. In contrast, the urban women in Zambia had a lower though not significant risk for discontinuation and pregnancy.

We conclude that it is difficult to predict autonomy, pregnancy, and discontinuation for African women who use NFP on the basis of socioeconomic variables. An often-used indicator for successful use, family planning intention, was never significant in explaining increased or reduced risk in this multivariate model. However, successful use of NFP was associated with possible program improvement over the life of the project and client visit intensity.

Measuring natural family planning in terms of couple-years of protection

Lilia I. Cuervo, MA

New York, New York

Couple-years protection is a summary index of contraceptive protection. Couple-years protection allows comparisons of natural family planning with other methods. One couple-year protection for condoms is equal to 1 couple-year protection for pills and 1 couple-year protection for natural family planning. Critical in the calculation of couple-year protection for natural family planning is average duration of use. A working group on natural family planning recommended that 2 years of use be used as average duration until more data are available. (AM J OBSTET GYNECOL 1991;165:2063-5.)

Key words: Natural family planning; couple-years protection

What is couple-years protection?

Traditionally, family planning programs are evaluated with indicators such as numbers of users, client contacts, service outlets, and volume of contraceptives distributed. Evaluation measures like these, however useful, provide neither a summary picture of contraceptives dispensed nor a summary of the protection provided to clients through each type of method, much less through a mix of different methods. For example, how does one compare giving 10 condoms to one user and one cycle of oral contraceptive pills to another user?

The need for a simple summary index of contraceptive protection was successfully met by Samuel M. Wishik with the development of the couple-years protection (CYP) index. According to Wishik, the index is a composite measure of "person" (i.e., couple) and "time" (i.e., year) and, one could add, of "method" (i.e., protection).

One CYP means that one couple does not conceive for 1 year: this concept allows comparison of contraceptive methods. One CYP for condoms is equal to one CYP for the pill. A CYP is a standard measure of contraceptive protection.

The transition from the quantity of a given contraceptive method distributed to clients and the standard measure of protection provided by that contraceptive is accomplished by means of the conversion factor. The conversion factor is one of the two elements in the calculation of the CYP. The other element is the number of contraceptives provided to users.

From International Planned Parenthood Federation, New York. Reprint requests: Lilia I. Cuervo, International Planned Parenthood Federation, 902 Broadway, New York, New York 10010. 6/0/34199

Definition and calculation of the conversion factor

The conversion factor is defined as "the average duration of protection provided by one application of the method." As an analogy, the conversion factor can be compared to the exchange rates that are used to convert different currencies into a standard currency. By transforming each quantity of a particular contraceptive into CYP, the conversion factor standardizes the protection that is provided by each method in terms of CYP. Not only can the CYP for one method be compared with the CYP for another method, but the CYP for all methods can also be added to summarize the total CYP achievements of a program.

For barrier methods (e.g., condoms and vaginal tablets), each unit of application protects the couple for one act of intercourse only. The value of the conversion factor therefore is inversely dependent on the coital frequency of the couples. Thus if the coital frequency of the couples was 100 times per year, the conversion factor would be higher than if the coital frequency was 144. According to the definition of the conversion factor in the first case, the calculation would give, 1/100 = 0.01, and in the second case, 1/144 = 0.007.

In the case of injectable contraceptives, in which the duration of protection of each unit depends on the duration of effectiveness of the dose, the conversion factor is independent of coital frequency. In this case one needs to know how many doses are needed to protect the client for a year. If the injectable contraceptive protects for 3 months, four units will be needed, and the calculation of the conversion factor would be 1/4 = 0.25. In the case of oral contraceptives, the same procedure applies except that instead of four units for the year, 13 are needed, since this is the number of cycles needed to protect the couple for 1 year.

2064 Cuervo December 1991 Am J Obstet Gynecol

Table I. Natural family planning CYP achievement with different conversion factors

Type and number of acceptors		Conversion factor	CYP*
Example A	Lancaster		
Learners	177	0.9	159.3
Autonomous	265	5.7	1510.5
Total	442		1669.8
Example B	Working group		
Autonomous	265 1	2.0	530.0

*CYP = number of acceptors multiplied by the conversion factor.

For other semipermanent methods such as the intrauterine device (IUD) and Norplant, the conversion factor is independent of coital frequency and its value is directly related to the length of retention of the device in situ. The conversion factor for sterilization is based on the average age of the women who have been sterilized, subtracted from the age at menopause.

Calculation of the conversion factor for the natural family planning method

With the exception of NFP, there is a always tangible contraceptive unit (e.g., a cycle of pills, a condom, a diaphragm, a surgical procedure performed, etc.). For NFP, however, the effectiveness and continuation of use depends in great part on the quality of the teaching, on the clients' correct use of the method, and on the staff support that is given to clients. How do we know then what elements to include in the calculation of the conversion factor for this method?

Experience from the field indicates that there are two important elements to consider when the NFP conversion factor is calculated. The first is the distinction between the number of acceptors who are learners and the number of acceptors who are already autonomous. The second element is the duration of practice of the method by each type of acceptor.

The numbers of learners and autonomous users can be gathered from the program statistics. However, the calculation of the average duration of use requires long-term observation and follow-up of acceptors and clear definitions of the various events such as cases in which clients are lost to follow-up or drop-out for personal reasons or because of pregnancy, which can occur during the observation period. As with intrauterine devices and Norplant, life tables² or event calendars³ are used to determine duration of use.

Natural family planning acceptors: Learners and autonomous

According to the current literature on NFP, a learner is a person who registers in a program, attends instruction sessions, charts a certain number of cycles, and remains in the program for a given number of months. An autonomous acceptor is a person who has successfully completed the course of instruction and who is able to practice the method without assistance. In other words, the autonomous client correctly observes the signs of fertility and with her partner adjusts sexual behavior to achieve their family planning intention.

Observed values of duration of practice by acceptors of natural family planning

Much debate still exists about the average duration of protection that is conferred by NFP. Nevertheless, recent studies of good-quality NFP programs with strict definitions of discontinuation have achieved encouraging rates of continuation and effectiveness. For example, among the autonomous clients of the Saint Joseph's Hospital's NFP project in Lancaster, Pennsylvania, the average duration of practice of the method was found to be 5.7 years. For those who did not meet the requirements for autonomy, the average duration was only 0.9 years. More recently, Kambic and Martin found that the average length of use of "avoiders" was 3.10 years in Liberia and 2.72 years in Zambia, whereas for the learners, the durations were 0.71 and 1.12 years in these countries, respectively.

In the absence of special local studies, the recommendation of a working group that attended a seminar on cost-effectiveness of NFP and breastfeeding was "to assume two years of protection, based on the experience in the studies presented, until program data are available." The group also recommended that "costs and effects may be limited to the limiter/spacer proportion of the program."

Calculation of natural family planning CYP achievement

Table I shows that once data on the number of learners and autonomous acceptors and the average length of use are available, the calculation of the CYP achievement is quite simple. As indicated in Table I, it is done by multiplying the number of acceptors by the conversion factors.

Table I provides two examples of how to calculate a program's CYP achievement. In example A, the program has recruited 177 learner acceptors and 265 autonomous acceptors. By way of illustration, the conversion factors from the study in Lancaster, which was mentioned above, are used. The results indicate that, in this particular case the CYP achievement by learners was 159.3 and by the autonomous acceptors was 1510.5. Therefore the total CYP achievement in this program was 1669.8.

In example B, the program does not have figures of continuation for learners and autonomous acceptors; therefore, according to the recommendation of the

working group, the conversion factor of 2 years is aplied to the 265 autonomous acceptors. The result is 530 CYP or 57.7% less than in example A. If instead of the conversion factor for the Lancaster program one uses the conversion factor for Zambia, the results show CYP for learners of 198.3 and for autonomous acceptors, CYP of 720.8, for a total of 919.1 CYP.

In light of the above, it seems advisable that programs that offer NFP and meet the conditions below undertake the necessary studies on continuation of use of the method to calculate their own conversion factors. The conditions are:

- Both the population that is served by the program and the staff members who manage it know NFP well.
- · Special attention is given to the education and followup of acceptors. To do this, the institution maintains a good statistical system as well as a good network of communications and support for the clients (both for the acceptors and the spouses or partners) that is represented by counseling sessions and follow-up visits or calls.
- The medical and paramedical professionals who deal with the acceptors are sufficiently versed in the advantages and disadvantages of the NFP method and are also well disposed toward the clients.

• The clients are screened according to certain characteristics that predispose them to better acceptance and continuation of the method.

The decision on whether or not to undertake continuation studies and on whether or not to use the standard conversion factor of 2 years remains in the hands of program administrators and evaluators who know their programs.

The modified mucus method in India

Kathleen Dorairaj, MD

Ghaziabad District, India

The modified mucus method—Prajanan Jagriti (fertility awakening) is intended to serve the cultural needs of illiterate and semiliterate women. Over 10 months, 3003 women in northern India were taught the modified mucus method. There were a total of 42 pregnancies in 24,702 cycles for a Pearl index of 2.04. High effectiveness is attributed to the support that was provided to clients by the instructor. (AM J OBSTET GYNECOL 1991;165:2066-7.)

Key words: Natural family planning; India; Prajanan Jagriti modified mucus method

In India, there is a need for a range of family planning methods to cater to cultural and sociodevelopmental differences in the country. The modified mucus method (MMM), referred to as Prajanan Jagriti in India, is intended to serve the cultural needs of illiterate and semiliterate women who have a low status in the family. It was developed to improve the acceptance of natural family planning (NFP) among nonacceptors of family planning, specifically poor women with low levels of intraspouse communication and whose husbands have little motivation for family planning.

The method is based on the woman's observation of cervical mucus and is similar to other mucus methods. However, there are some critical differences between the MMM and other more established NFP methods. Unlike other NFP methods, the MMM does not require a woman to chart her menstrual cycle. The MMM has a simplified set of rules for avoiding pregnancy and requires fewer days of abstinence per cycle than other NFP methods. It is believed that the simplicity and the reduction in abstinence will increase acceptability of the MMM.

Methods

The method is based on the woman's observation of cervical mucus, which she learns to do in a series of 10 home visits with the MMM teacher over three menstrual cycles. The visits are scheduled to coincide with the phases in the woman's cycle when she is most likely to need help with her observations and support in the use of the method. The rules of the MMM are less conservative than those of the ovulation method when pregnancy is not desired. The MMM allows sexual relations in the first month of use; the ovulation method does not. The MMM allows sexual relations on preovulatory days when thick or sticky mucus is present

From the Natural Family Planning Association of India. Reprint requests: Kathleen Dorairaj, MD, NFP Association of India, No. 31, Sector 37, Arunvihar, Noeda 201-301, Ghaziabad District, UP, India. 6/0/34201 in women who have regular cycles; the ovulation method does not. And the MMM allows sexual relations on the third day after the "feeling of wetness stops." The ovulation method rule is to wait until the fourth day after mucus peak. The greatest difference between the MMM and other NFP methods is that the MMM is seen as an entry point into the personal development process for poor, illiterate women. It does this by making women aware that they have power to control reproduction and by teaching them to use this power to better their lives.

Because the MMM is designed for use by illiterate women, it uses a structured approach to teaching and learning, and the timing and content of client visits are specified for the teacher. The structured approach to teaching the MMM and the supportive counseling that is given to the users may contribute to improved effectiveness compared with other NFP methods.²⁻¹

This study of 3003 acceptors was a part of the Training and Action Pilot Project for nonCatholics in North India, Uttar Pradesh, and Madhya Pradesh; the project covered 40 villages in six districts.

A training and action project was designed to train nonchurch, nongovernmental groups that are close to the grass roots to teach fertility awareness and NFP as an entry point to women's personal development. The project had a research component in which the acceptance and use-effectiveness in rural women was to be studied. The training project was used to mobilize women leaders by means of the infrastructure of small, grass-roots-level nongovernmental organizations. A systematic approach was used to select and train personnel including cluster coordinators and village leaders.

Results

In 10 months, 3003 menstruating women of proven fertility were taught fertility awareness and the use of the MMM. To ensure follow-up, teaching of the method was restricted and therefore the sample was contained. Only 10 new acceptors were taught each

month by each of the 37 village women leaders, who were supervised by 12 part-time cluster coordinators. All of the 3003 women completed the first 3 months of training. There were no unplanned pregnancies or drop-outs in the first month.

There were a total of 42 pregnancies in 24,702 cycles for a Pearl index of 2.04. The unplanned pregnancies occurred mainly in the women who had no living children and rarely in women who had one child.

The causes of unplanned pregnancy were considered to be:

- 1. The low motivation for family planning and the high psychologic need to prove fertility by having
- 2. The longer periods of fertility among young
- 3. The husband's difficulty in abstaining from sexual
- 4. The short duration of marriage and poor intraspouse communication.

The use-effectiveness of the method can be attributed to:

- 1. The motivational levels of the women/acceptors who had no alternative method available.
- 2. The teaching and support of the village women leaders.
- 3. The shorter periods of abstinence that were required because of the emphasis on the feeling of wetness.

Discussion and recommendations

During the discussion period, some meeting participants expressed concern that extraordinary efforts were being made to do effectiveness and continuation studies when in fact operations research might be more useful. Some argued that the use-effectiveness of natural family planning (NFP) is established and that resources should be redirected to informing the biomedical and population community about NFP.

Table I in Kambic's article shows that a number of use-effectiveness studies already exist. However, both Kambic's and Labbok's articles pointed out some of the difficulties in attempting to generalize these results; for example, the broad range of pregnancy rates, the number of cultures and conditions under which the studies were done, and the advent of simplified modified mucus method NFP methods. Furthermore, use-effectiveness and continuation rates can be calculated in the context of operations research studies and surveys. In the large demonstration projects in Liberia and Zambia, Kambic and Gray used resources efficiently to describe a variety of outcome measures including effectiveness. Thus additional effectiveness studies in NFP will be

necessary, and they can be done concurrently with other studies.

A second issue raised by participants was disparity between family planning intention and behavior of some NFP couples. Why do couples who say they want to avoid pregnancy continue to have intercourse during the fertile time? Trussell and Grummer-Strawn have shown that these couples who break the rules, "risk takers," are much more likely to become pregnant than those who follow the rules. Frank-Herrmann found that a large proportion of German couples fall into this category. Their risk-taking behavior belies what these women and couples say about wanting to avoid pregnancy.

However, most NFP experts agree that having intercourse during the fertile time is not necessarily an expression of an intent to become pregnant. Sexual intercourse is often an emotional and not a logical act, and intercourse during the fertile time is not a reason to classify a pregnancy as planned unless the couple so indicates before the fact. Future research should focus on identifying couples who are likely to take risks and interventions to help them use NFP successfully.

Abstracts*

Natural family planning training issues and strategies for the 1990s

Kimberly Aumack, Chair Mary Catherine Martin, Co-Chair Bonnie Pederson, Rapporteur

Introduction and overview of natural family planning training programs

Diane Vogelsang, BA

Quality natural family planning (NFP) instructor training is an essential component of NFP. There are several successful models for training NFP instructors. Synopses of four training programs are presented.

Competency-based approach to training and natural family planning instructor standards

Mary Catherine Martin, PhD

Competency-based natural family planning training programs are designed to prepare teachers to correctly demonstrate knowledge, supportive attitudes, and effective teaching skills.

An experiential approach to training natural family planning trainers

Kimberly Aumack, BA

To improve the quality of natural family planning (NFP) instructor training, the training division of the Institute worked with Western Consortium/International Health Programs to develop, conduct, and evaluate three international Training of Trainers programs. The purpose was to increase the NFP instructors' understanding of the training process, enhance their knowledge of NFP, and improve their skills in designing, conducting, and evaluating NFP instructor training courses. The training methodology used in these programs was based on current theories of adult education and experiential learning.

Preparing instructors to educate diverse client populations: The impact of culture, religion, socioeconomic status, and educational levels

Marie M. Mascarenhas, MD

Obstacles to widespread use of family planning in India include: limited access to services, cost, nonacceptability of many available methods, lack of information, and fear of side effects. Irrespective of caste or religion, most of the population practices different types of abstinence throughout their lives. There also are certain characteristics of successful natural family planning users in India. These factors should be included in natural family planning instructor training programs.

Training and supervision from small natural family planning programs to national service delivery systems

Sabina Mwaulu, RN

The Natural Family Planning Training and Medical Service Center in Nairobi, Kenya, conducts an instructors' training course for nurses employed by the Ministry of Health and other health and family planning organizations. The goal of the training is to develop natural family planning instructors who can provide high-quality services to their institutions' clients. Supervision after training is critical for program success.

Training evaluation: Its impact on future instructor training, client education, and natural family planning services

George Walter, MD

Training evaluation is a continuous process that includes needs assessment, monitoring, and evaluation of the immediate outcome of a course, as well as evaluation of the impact of training. The potential for multilevel evaluation to positively influence future natural family planning development in areas such as instructor training, client education, and service delivery is presented.

*The following abstracts of the nine sessions not contained in this JOURNAL are provided for your information. The nine sessions will be published, in their entirety, by Georgetown University in Spring 1992. For further information please contact Dianne Beekhuysen, Resource Center Coordinator, Institute for Reproductive Health, Georgetown University School of Medicine, Department of Obstetrics and Gynecology, 3800 Reservoir Rd., N.W., Washington, DC 20007; telephone (202) 687-1392.

Experiences and trends in natural family planning education and outreach

Rosalia Rodriguez-Garcia, Chair Leila Mehra, Co-Chair Earle Lawrence, Rapporteur

New directions for education and outreach in the 1990s

Rosalia Rodriguez-Garcia, MSc

Education and outreach are important to increasing awareness and use of natural family planning (NFP) and to reaching health professionals and policymakers. Two areas of intervention have emerged in the 1990s that could well make the difference between NFP remaining solely a method for a small and self-selected group of users or becoming a credible and widely used method: (1) empowerment of couples with fertility education and (2) use of sociodemographic data and sound communication strategies to increase the impact of NFP outreach programs.

Reaching new populations with natural family planning education

Leila Mehra, MD

Successful delivery of natural family planning (NFP) services is linked to education and understanding of the needs of special populations. Groups that are greatly in need of NFP services are identified: rural illiterate and underserved populations, young unmarried women and adolescents, and breastfeeding women.

Innovative approaches from population communication services: Implications for natural family planning

Benjamin V. Lozaré, PhD

To be effective, communication must be personal, popular, and persuasive. Entertainment-education is the key trend for mass communication as are computers for both interpersonal and interagency communication. Furthermore, entertainment for education must also be profitable.

Using quantitative data to define natural family planning use: A profile

Ravi K. Sharma, PhD

This paper addresses a twofold strategy to develop quantitative profiles of natural family planning (NFP) users: analyses of NFP service statistics and surveys that can provide retrospective information on NFP use.

Seeking opportunities for natural family planning expansion: The Serena experience

Suzanne Parenteau-Carreau, MD

The experience of the Serena natural family planning (NFP) program in Canada indicates that a multitargeted, comprehensive outreach program is very likely to succeed despite geographic distances and language differences. Outreach to decision makers and health professionals and direct advertising to reach concerned couples were key factors in the success of the Canadian NFP program.

Lessons learned from a mass-media campaign in Peru

Guillermo Tagliabue, MD

From June 1987 through June 1989, the main objectives of a recent study by the Asociacion de Trabajo Laico Familiar in Lima, Peru, were to: (1) improve dissemination of accurate and up-to-date information on responsible parenthood and natural family planning and (2) improve the training in natural family planning by means of specialized audio-visual materials.

Creating a demand for scientific natural family planning: The Zambian experience

Lubinda M. Tafira

There was very little demand for natural family planning before the Family Life Movement of Zambia began its 5-year demonstration program in 1981. However, the demand is higher today than the Family Life Movement of Zambia and its collaborating agencies can meet. This experience has taught us to be careful about creating a demand if there are insufficient resources to meet it. Today we are struggling with an expanding clientele with funds that have been cut by 60%.

Center for Research, Education, Service and Training's fertility education program for youth

Marie M. Mascarenhas, MD

Much pressure is exerted on India to control its population. To the illiterate although intelligent majority of Indians, our "biophilic" nature prevails—the love of family and life in the fields. Moreover, without the use of computers and statistics, rural couples have come to the correct understanding that to have three adult children, they must start with a family size of six children, because infant and child mortality alone takes a 40% toll, and with primitive methods of agriculture and fishing, a family needs three children to survive.

Teen STAR (Sexuality Teaching in the context of Adult Responsibility) year 4 cohort with one-year after program follow-up (United States) and report of Philippine cohort

Hanna Klaus, MD, and David Kardatzke, BSc

A study of 899 women and 308 men in the United States who participated in the 1988 to 1989 Teen STAR program indicates that the number of male and female subjects who engaged in sexual intercourse declined from entry to exit and 1 year after program. Similar but less significant results were obtained from a Philippine cohort. The results indicate that experiential learning of fertility delays teens' first sexual intercourse and reduces the number who continue to be sexually active.

Fertility education for young men

Stephen A. Burke, MSW

Young men are often overshadowed by the focus of fertility programs on women. What is taught, where, and who is taught, and who are the teachers are among the key factors that must be taken into consideration when planning fertility education for young men. For the sake of both young men and women, we need more balance in the content of fertility awareness programs provided to each gender. Young men's fertility signs, their strengths, insecurities, and role in relationships are often overlooked.

Training and educational materials

Lois A. Schaefer, Chair Margot L. Zimmerman, Co-Chair Ron Magarick, Rapporteur

Issues in the development and dissemination of training and educational materials

Lois A. Schaefer, MPH

As natural family planning begins to serve a more diverse clientele, appropriate education and training material are needed. Distribution of these materials, particularly those intended for worldwide or regional audiences, is a complex process. Planning for distribution should begin when materials are being developed.

Materials development, testing, and evaluation: An overview

Margot L. Zimmerman, BA, and Premila Bartlett, MPH

The Program for Appropriate Technology in Health's extensive experience in materials development is presented to illustrate the steps necessary to produce acceptable, relevant, and understandable materials. Three stages are given particular emphasis: the need for target audience reseach, involvement of members of the target audience in the development process, and ongoing pretesting and revision of materials.

Materials translation: Is that really what you want to say?

David Bowen, PhD, and Margareta Bowen, PhD

Translating written text or interpreting spoken material requires great care. Not only is knowledge of languages needed, but familiarity with the subject matter will also contribute to the quality of the final product. Professional translators are preferred, especially for major languages, because there are many difficulties inherent in the use of volunteers and native informants. When testing a translator's abilities, comprehension tests are preferable to back-translation.

Introduction of natural family planning information into multimethod materials for trainers

James Lea, PhD, and Catherine Murphy, MEd

The Program for International Training in Health materials for family planning trainers addresses a broad menu of contraceptive methods and a wide variety of service delivery settings, adapted to the country in which they will be used. Fertility awareness is taught as the basis for all methods; natural family planning is presented individually as one of the methods. Recognition of the need for specialized training in natural family planning and the broad service responsibilities of most health workers has led to an emphasis on a broad knowledge base and referral rather than on direct delivery skills.

Experiences in the field: Confederacao Nacional de Centros de Planejamento Natural da Familia, Brazil

Maria J. Sogayar, MAB

In Brazil, Confederacao Nacional de Centros de Planejamento Natural da Familia has developed a successful program by adapting its natural family planning teaching and materials to the audience. Materials are simple, with complex ideas of fertility illustrated by naturally occurring events that are familiar to users.

Materials development in Zambia: Concept versus reality

Lubinda M. Tafira

The Family Life Movement of Zambia's 5-year demonstration program to provide natural family planning services was the first of its type and scope in Africa. All the training materials were developed as the practical needs of the trainers, trainees, and users became evident. Today's elaborate text books and picturesque volumes were not available then; thus the Family Life Movement of Zambia began by developing its own materials. Later, the World Health Organization's Family Fertility Learning Resource Package was introduced and adapted to meet local needs.

The development of the International Federation for Family Life Promotion training guide

Mary Catherine Martin, PhD

In 1974 the Human Life Foundation with the Department of Health and Human Services, Office of Family Planning, and in collaboration with the International Federation for Family Life Promotion, began work on its document, *Instructor Training in Natural Family Planning (NFP)*. A task analysis of NFP programs and teachers in the United States and Canada was conducted. It revealed that teachers need to have sufficient and accurate knowledge and skills in fertility awareness to effectively teach ovulation and symptothermal methods to couples and provide follow-up services until couples reach autonomy.

The "Guide for Natural Family Planning Trainers"

Kimberly Aumack, BA

The ultimate goal of natural family planning instructor training and supervision is to ensure the provision of quality services. The likelihood of achieving this goal is greatly enhanced if the training courses designed for natural family planning instructors actually enable them to develop the knowledge, attitudes, and skills needed to effectively teach clients.

Service delivery part 1: Current programs and strategies for expansion

Gloria Mejia, Chair Antonio Solis, Co-Chair Richard Sevigny, Rapporteur

Materials in the United States: An example from Los Angeles

Carmen Minervini, BA

In the United States today, the natural family planning (NFP) provider serves people from diverse backgrounds. No longer is NFP solely the method for Catholics; it has become an issue of healthy birth control as well.

Client teaching materials for francophone Africa

Isabelle Ecochard, MD

A large portion of the population in francophone Africa has limited literacy skills and therefore requires highly visual and pictorial teaching aids. Materials for this population do not have to be complex to be effective, but to maximize comprehension and the effectiveness of natural family planning, they need to be easy to use and understand.

Materials for the modified mucus method

Kathleen Dorairaj, MD

In India, the potential acceptors of the modified mucus method have been identified as poor illiterate and semiliterate women living in remote villages. These women are nonacceptors of family planning because of low personal motivation, low motivation of the husband, or nonavailability and inaccessibility of family planning methods and services suited to their needs.

Current natural family planning programs and strategies for expanding service delivery: An introduction

Gloria Mejia, MD, and Antonio Solis, MD

Natural family planning (NFP) services are provided through an increasing variety of public and private sector programs, including community-based programs, Ministries of Health, family planning programs, religious-based programs, and others. To improve the availability of NFP services and increase the options for family planning clients in the 1990s, NFP programs must be offered through a variety of channels. The purpose of this session is to identify the gaps in current NFP service delivery and to summarize recommended strategies to expand NFP programs.

Natural family planning in a family planning program

Thomas Kring, BD/MTH

The Los Angeles Regional and the California Family Planning Councils oversee a network of state and federally funded programs through which more than 200 clinics in California provide free or low-cost family planning services. Included in the full range of services offered are natural family planning and fertility awareness. We believe that clients need to receive education about all methods, but the ultimate responsibility for method selection, as for all health care, rests with the individual.

New approaches to expanding natural family planning

David F. Skipp, BA

New approaches can be used to expand natural family planning service delivery and to develop more effective programs. To lower costs, offer higher quality services, and provide greater coverage for a "well-defined market," it is important to analyze existing natural family planning programs, research current operations, and test new approaches. This paper includes innovative ideas to use existing resources and to generate new or additional outside resources.

Abstracts 2073

Natural family planning: National program development in Kenya

Rose Wahome, RN, and Sabina Mwaulu, RN

In Kenya, the Catholic Church provides nearly one third of the total health services: close to 97% of these services include natural family planning (NFP). For the past 10 years, the Kenya Catholic Secretariat has opened more than 500 teaching centers, which include approximately 1300 volunteer NFP teachers and more than 74,000 registered NFP clients. More recently, NFP services have become available through public sector health services whose personnel are trained by the NFP Training and Medical Services Center.

Natural family planning through the health sector in India

Maria M. Mascarenhas, MD

Community health is a priority in India. The goal of the community health workers is to facilitate the emergence of a "self-energized family," of which fertility knowledge and natural family planning are an important part. Fertility awareness and natural family planning should be integrated into educational programs at all levels, along with other efforts to improve the health and status of women within both the family and the community.

Natural family planning through the health sector in Brazil

Maria J. Sogayar, MAB

In Brazil, legislative support for natural family planning (NFP) has increased the availability of NFP in the health sector. State and national laws ensure the provision of natural methods of family planning. As a result, responsibilities of the Confederação Nacional de Centros de Planejameto Natural da Família for planning and conducting NFP instructor training have expanded throughout the country. In addition, they provide NFP support and assistance to government and private organizations.

Expanding natural family planning through vocational schools for women in Cote d'Ivoire

Rosalia Rodriguez-Garcia, MSc

In Cote d'Ivoire, the Mouvement pour la Promotion de la Vie Familiale and the Ministry of the Promotion of Women introduced natural family planning (NFP) education into the national system of women's home economics centers and vocational schools. As of December 1990, 5000 women received fertility education, 837 were registered NFP users, and 389 were autonomous users. As a result of this project, a teaching module on fertility education and NFP has been officially integrated into the 2-year curriculum of the vocational schools of the Ministry of the Promotion of Women in Cote d'Ivoire.

An American national experience: Natural family planning services under the auspices of the Roman Catholic Church

Theresa Notare, MA

Natural family planning (NFP) services are offered under the auspices of the Roman Catholic Church in the United States to minister to married Catholics. The national office, the Diocesan Development Program for NFP, was formally established in 1981 by the National Conference of Catholic Bishops. Its mandate was to assist Catholic dioceses in increasing efforts to make NFP more widely known, respected, and used. A variety of projects enable the Diocesan Development Program to continue its work. There is an NFP coordinator or contact person in each of the 187 dioceses in the United States.

Service delivery part 2: Elements necessary for success

Victoria Jennings, Chair Shelagh O'Rourke, Co-Chair Richard Sevigny, Rapporteur

Introduction: Principles for meeting increased demand

Victoria Jennings, PhD, and Shelagh O'Rourke, PhD

It is expected that the demand for family planning will increase from 192 million users in 1990 to 286 million in 2000. The Agency for International Development has identified five principles on which family planning services must be based to meet this increasing demand. These principles, which apply to all family planning services including natural family planning, are that service delivery must (1) emphasize the quality of care; (2) expand to serve larger populations in more cost-effective ways; (3) evolve to accommodate a diverse, younger population and improved method mix; (4) include cooperation by all sectors, that is, government, private voluntary organizations and forprofit groups; and (5) be sustainable.

A management needs assessment for African natural family planning programs: Process and results

Darryl N. Pedersen, BA

Results of a management needs assessment of eight natural family planning programs in Africa indicate that these programs require technical assistance and training to improve their ability to analyze unmet need, quantify their objectives, evaluate the results of their efforts, and develop budgets and management plans linked to their objectives. Donors should streamline technical assistance to natural family planning programs. Program managers must be committed to improving their management practices.

Targeting quality of care: A strategy for successful periodic abstinence services

Zoe Kopp, MPH

Quality of care is an important concept in providing periodic abstinence whether services are provided by a natural family planning group or by a family planning group. Six elements of quality of care are relevant: (1) choice of methods to increase acceptability, (2) informing and counseling clients to improve effectiveness, (3) technical competence of providers, (4) personal relations between providers and clients, (5) mechanisms to encourage continuity, and (6) appropriateness and acceptability of services. Considering these factors can help programs provide women and couples with a safe, effective family planning method.

The effect of supervision on program development and quality of services

Richard St. Mart, BSc

Supervision is a vital link between program management and service delivery. It also links members of the organization into a team that provides high-quality, cost-effective services and efficiently achieves the organizations' goals. Through its supervision system, Action Familiale has improved service quality, decreased drop-outs and staff turnover, and decreased the amount of time for clients to reach autonomy in natural family planning use.

Automated management information systems

James Nesbitt, PhD

Programs should develop a sound manual management information system before they convert to a computerized system. Both manual and computerized systems should (1) be designed for specific management purposes, (2) collect data related to these purposes, and (3) focus on processes that influence the organization's ability to provide services effectively and efficiently. Commitment from top management to use and learn from the information generated by the system is crucial for success.

Adapting data systems of multimethod programs to incorporate natural family planning

Lilia I. Cuervo, MA

Including natural family planning (NFP) in data systems of multimethod family planning programs is an important step in increasing availability of NFP services. Among family planning associations in Latin America affiliated with The International Planned Parenthood Federation, the number of new NFP acceptors reported in program statistics increased significantly when family planning associations were encouraged to include this information and were given "credit" for providing NFP services. To incorporate NFP into a multimethod data system, family planning programs need to be shown the institutional, pro-

Cuervo (cont.)

grammatic, and political benefits of offering NFP. Reporting space for NFP should be provided in statistical forms, and the results of the programs' NFP efforts should be tabulated, analyzed, and publicized.

Budgeting and financial planning in natural family planning programs: In search of the perfect system

Darryl N. Pedersen, BA

Budgeting and financial planning are the central elements of good management. Although development programs must have technical commitment and merit to succeed, they must be well managed to have a significant, sustainable impact. Not-for-profit institutions must take their fiduciary responsibility seriously. The same budgeting and financial management tools that are applicable to other development efforts are applicable to natural family planning programs. Using these tools, managers can establish clear linkages between costs and resources, resources and activities, and activities and results. This is critical for all phases of the planning-implementation-evaluation process.

Policy issues in natural family planning

Victoria Jennings, Chair Lelia Mehra, Co-chair Paul Gross, Rapporteur

Gaining policy support for natural family planning

Victoria Jennings, PhD

Sustained success in any development effort requires support from relevant policymakers. Those who make decisions about resource allocation both in international donor and membership organizations and in specific countries and local institutions must (1) recognize the importance of a particular development effort and (2) take steps necessary to create an environment for its success. Natural family planning (NFP) is no exception. In fact, given many commonly held perceptions and the lack of accurate information about NFP, policymakers are often a barrier to the growth and availability of NFP services.

Natural family planning: Agency for International Development policy considerations

Sarah Clark, PhD and Jeffrey Spieler, MSc

The Agency for International Development support for natural family planning (NFP) is based on the principles of voluntary and informed choice. The Agency for International Development provides 5 to 6 million dollars annually for NFP and includes NFP in all areas of its programming, including research, information and training, service delivery, policy, and technical assistance.

Policies and support for natural family planning: Rationales and future plans

Jose Donayre, MD

The United Nations Population Fund supports natural family planning (NFP) as one of many important family planning options. There is a natural constituency for NFP, and NFP should be provided to meet their needs. Especially important is that the knowledge that NFP provides to women about their reproductive functions and the alternative reproductive and family formation behavior related to NFP empower women to exercise independence in setting their reproductive life course.

International Planned Parenthood Federation's policy and support for periodic abstinence: Rationale and future plans

Zoe Kopp, MPH

The International Planned Parenthood Federation acknowledges the importance of periodic abstinence-based family planning methods and encourages its members to make these methods available to increase family planning options. Couples who choose these methods should be informed of their advantages and disadvantages, including failure rates, and appropriate counseling and follow-up should be provided.

World Health Organization's policy considerations in natural family planning

Leila Mehra, MD

The World Health Organization (WHO) is continuing its leadership role in promoting and supporting the development of an integrated approach in maternal and child health and family planning programs, including natural family planning. Through its relationship with member countries, the WHO is taking specific actions to ensure that natural family planning information and services are available to those who choose to use them.

Understanding policy and the policymaking process: Considerations for initiating policy interest

Rosalia Rodriguez-Garcia, MSc

Initiating and sustaining policy action to support natural family planning are essential. Yet many policy-oriented efforts are unsuccessful because of the lack of understanding about what policy is and the context in which policymakers work. This article provides an overview of some of the considerations that are key to initiating policy interest for natural family planning.

Communicating with developing country policy-makers: The case for natural family planning

Elaine Murphy, PhD

Appropriate, effective communication with policymakers is essential for successfully introducing innovations, including natural family planning. Objectives must be clear, audiences must be identified, messages must be relevant to the audience, the source of the information must be appropriate, the channel of information must reach the desired audience, and the format must be compatible with the audience, the message, and the channel.

From policy to norms to services: Developing a consensus for natural family planning

David F. Skipp, BA

The climate for natural family planning (NFP) can be improved by working through the policy process, from official policy statements to the norms directing the actions of institutions responsible for implementing that policy, and finally down to the level of actual service delivery. All these levels must be addressed to ensure the availability of NFP as a family planning option.

XV. Roundtable discussions

Diane Vogelsang, Chair

The missing link—Why natural family planning is still "The best kept secret"

Kay Ek

This topic focused on the reasons why natural family planning has not been more successfully promoted and accepted by both the private and public sectors. Ways in which to present natural family planning in more positive ways were explored.

Making periodic abstinence more acceptable to natural family planning users

William Uricchio

Periodic abstinence has often been designated as one of the major barriers to broader acceptance of natural family planning. During this session, the group discussed ways to address the subject of periodic abstinence in a more positive light, stressing the benefits that can lead to strengthening the marital bonds, as well as enhancing the emotional and sexual aspects of marriage.

The fertility awareness method: Extent of use, potential, and research needs

Nancy Williamson

The fertility awareness method involves identification of the fertile period and the use of a temporary barrier method during the fertile phase rather than abstinence. Because this method is rarely taught in either natural family planning or family planning programs, there are no agreed on standardized instructions. As a result of this session, research priorities for the fertility awareness method were proposed.

Toward better marriages through natural family planning

Irene Osmund-Ruiz

The scientific basis of natural family planning (NFP), its effectiveness, and safety have been established. A new goal now is to establish the acceptability of NFP and its benefits in enhancing communication and understanding among married couples. Making known the positive aspects of NFP should help achieve this goal.

Providing natural family planning counseling within a family planning clinic

Carmen Minervini

In the past there has been concern that teaching natural family planning in a family planning clinic would be difficult. It was believed that a contraceptive mentality would undermine the philosophy that natural family planning is a way of life and that people working in a family planning clinic would not understand the need for abstinence.

A pilot study on teaching natural family planning in general practice

Cecilia Pyper

This discussion was opened with a brief description of a pilot study conducted in general practice in Oxford, England, from 1986 to 1988. The study confirmed that it was feasible for a nurse to teach natural family planning within a health care system and that group teaching was possible for some couples. The study showed a need for a well-structured course as well as audio-visual aids to reduce instruction time.

At what stage is natural family planning service delivery?

Hanna Klaus

For the past decade or so, publicly funded natural family planning programs have been at the level of demonstration projects. Funding agencies wished to have highly scientific, verifiable protocols and procedures to be able to justify awarding monies.

Klaus (cont.)

In the process, some believe that the delivery of natural family planning services has become secondary to the documentation of the delivery and effectiveness of the services.

Various forms of financial support for natural family planning teachers

Claude Lanctôt

In many countries around the world, natural family planning services, because of their essentially educational characteristics, have primarily been developed in nonclinical settings by a group of interested volunteers. There is a wide range of remuneration for natural family planning teachers, from the strictly volunteer to the fully salaried.

The promotion of exclusive breastfeeding and the lactational amenorrhea method in natural family planning programs

Kathy Kennedy

The purpose of this group discussion was to generate ideas about potential obstacles to the promotion and use of the lactational amenorrhea method through natural family planning programs and possible ways to overcome such obstacles.

Social science natural family planning issues

Ravi K. Sharma, Co-chair Jeffrey Spieler, Co-chair Nancy Williamson, Rapporteur Rochelle Shain, Rapporteur

Overview of social science and behavioral issues in natural family planning

Ravi K. Sharma, PhD, and Jeffrey Spieler, MSc

The number and characteristics of people who use natural methods is an important issue in natural family planning (NFP). National surveys of health and contraceptive use, such as the Demographic and Health Surveys and the Contraceptive Prevalence Surveys, provide some insight into this issue, particularly in countries in which reported use of periodic abstinence is high. From these surveys, the percentage and characteristics of women in a country or region who use (or have ever used) NFP can be determined and compared with users of other methods. Recent surveys also indicate the degree of accuracy of women's knowledge of their fertile and infertile days. Another important issue is a psychosocial factor that may affect choice, use, and continuation of NFP. This issue is difficult to study cross culturally but has significant implications for service delivery, teacher training, and counseling. This session addresses social science issues and proposes research questions that could investigate them more thoroughly.

Abstracts 2077

Volume 165 Number 6, Part 2

Knowledge and use of periodic abstinence

Martin Vaessen, PhD

The data on periodic abstinence collected by the Demographic and Health Surveys program include knowledge and use of periodic abstinence, use of modern contraceptives, method failure, and perceived problems associated with periodic abstinence.

Natural family planning use in Peru

Ravi K. Sharma, PhD

Natural family planning, which is used by a significant percentage of Peruvian couples, is discussed in terms of the sociodemographic characteristics of the respondents interviewed for the 1986 Demographic and Health Survey. Data show that natural family planning use and knowledge of the fertile period are positively related to women's education. Respondents also expressed concern about the perceived side effects of modern contraceptives.

The 1991 Mauritius contraceptive prevalence survey

Charles Chen, PhD, Jay Friedman, MPH, J. Shanker, BA, S. Kalasopaten, PhD, and Leo Morris, PhD

In 1985, Mauritius had an overall contraceptive prevalence rate of 75.3%, with 17.1% of currently married couples practicing natural family planning (NFP). Because this island nation has one of the highest prevalence rates of NFP among the developing countries, the 1991 Mauritius Contraceptive Prevalence Survey questionnaire will include a special module for both NFP and breastfeeding. Also, using a 5-year calendar, continuation rates and the use-effectiveness of NFP in this country will be evaluated. A review of results from the 1985 survey and analysis plans for the 1991 survey are discussed in this paper.

Psychosocial factors in natural family planning: An overview

Ravi K. Sharma, PhD

Based on existing research, psychosocial factors that influence the adoption, continuation, and effective use of natural family planning are summarized according to whether they are user, method, or context-related factors. Data are lacking on many of these variables. Many existing studies are methodologically and theoretically deficient.

Psychosexual aspects of natural family planning as revealed in the World Health Organization multicenter trial of the ovulation method and the New Zealand continuation study

Margaret M. France, MA

Psychosexual factors, particularly those related to abstinence, influence the effectiveness and acceptability of natural family planning. These factors have been examined by the World Health Organization multicenter study of the ovulation method and the New Zealand continuation study. Results of these studies are compared.

A profile of successful versus unsuccessful ovulation method users: Factors associated with unplanned pregnancy and nonadherence to the rules

Miriam H. Labbok, MD, MPH, Alfredo Pérez, MD, and Hanna Klaus, MD

This study identifies factors associated with the occurrence of unplanned pregnancy during use of the ovulation method of natural family planning (NFP). These include menses return, especially during breastfeeding, young age, and lack of previous experience with family planning. Whereas youth and lack of previous family planning are also associated with nonadherence to the rules, during the period of menses return, couples appear to be following NFP rules closely. These findings raise questions concerning the possibility of targeted counseling and special self-help groups, such as men's support groups, for subsets of the method acceptors. These findings also raise concerns about method rules during high-risk periods, such as lactational menses.

Operations research in natural family planning: Strategies, issues, and research approaches

Ed Ricci, Chair Myrna Seidman, Co-chair Mary Ann Sevick, Rapporteur

Current status of operations research in natural family planning

Ed Ricci, PhD, and Myrna Seidman, MPH

Although operations research (OR) has been widely used by family planning programs to improve program efficiency and acceptability, it has been applied minimally to natural family planning (NFP) programs. Although numerous factors inhibit the use of OR in NFP, the positive impact of these studies in family planning programs suggests that NFP should use OR to investigate issues of interest to the field.

Natural family planning program format effectiveness

Don Kramer, MST

This study compares the cost-efficiency and family planning outcomes of the Creighton Model of natural family planning and a team teaching format. Although the team teaching model was more cost-efficient, family planning outcome was identical in both models.

A pilot study on teaching natural family planning in general practice

Elizabeth M. Clubb, MD, Cecilia M. Pyper, MD, and Jane Knight, RN

This study examines the feasibility of teaching natural family planning in a general medical practice. Results showed high rates of use-effectiveness and relatively low cost. Additional benefits are helping couples with difficulty conceiving to achieve pregnancy, and assisting young women to better understand their own sexual development.

Evaluation of natural family planning programs in Liberia and Zambia

Robert T. Kambic, MSH, Ronald H. Gray, MD, Claude A. Lanctôt, MD, Mary Catherine Martin, PhD, Roselind Wesley, and Richard Cremins

A 5-year demonstration project was conducted to evaluate the use and cost-effectiveness of natural family planning in Liberia and Zambia. Pregnancy rates of 4.3% and 8.9% and costs of \$40.00 and \$30.00 per user were achieved in Liberia and Zambia, respectively.

Using operations research to improve natural family planning program services, management, and policy

Maria Wawer, MD, Theresa McGinn, MPH, and Regina McNamara, PhD

Operations research can be applied to natural family planning (NFP) programs. Results of operations research studies conducted in family planning settings can often be generalized to NFP. Because of the differences between NFP and other family planning methods, it is also important to identify particular problems of NFP programs and to develop and test solutions to address these problems.

Political and practical issues in the implementation of operations research studies in natural family planning

John Townsend, PhD, and Ricardo Vernon, PhD

Operations research (OR) has not been an important component of natural family planning (NFP) research. Most NFP services are provided by church-related institutions in which pastoral issues are more important than service expansion and effectiveness. Although NFP programs have limited resources and capability to conduct OR, these programs can learn much from the studies conducted by family planning programs. An OR study of NFP service delivery in Colombia is reviewed.
